

## 3D non-LTE abundances in metal-poor stars

*Monday, 3 December 2018 16:50 (30 minutes)*

Stellar abundance measurements are heavily model dependent, and for late-type stars, and especially for metal-poor late-type stars, the accuracy is often limited by the use of one-dimensional (1D) hydrostatic model atmospheres and the assumption of local thermodynamic equilibrium (LTE). Recently it has become feasible to relax both assumptions simultaneously, i.e. to perform 3D non-LTE spectroscopic analyses. In this talk I shall discuss the physics of this more accurate method and review recent developments, including our latest results for carbon, oxygen, and iron abundances in the metal-poor halo.
