# Matter-Antimatter Asymmetry

The asymmetry is described quantitatively by,

$$\eta = \frac{n_b - n_{\bar{b}}}{s} \simeq 8.5 \times 10^{-11}$$

#### The Sakharov Conditions

- Baryon number violation
- 2  $\mathcal{C}$  and  $\mathcal{CP}$  violation
- Period of non-equilibrium

## Ratchet Mechanism

Inspired by molecular motors in biological systems, and their ability to generate directed motion.

- Consider an inflaton and complex scalar carrying *L* charge during reheating.
- A derivative coupling between a complex scalar and inflaton.
- Directed motion in the complex scalar phase gives a non-zero *L* number density.

## The Model

Interplay between the inflaton and complex scalar during reheating,

$$\begin{split} S &= \int dx^4 \sqrt{-g} \left[ g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi^* - V_0(\phi, \phi^*) \right. \\ &\left. + \frac{1}{2} g^{\mu\nu} \partial_\mu \Phi \partial_\nu \Phi - U(\Phi) + \frac{i}{\Lambda} g^{\mu\nu} \left( \phi^* \overleftarrow{\partial_\mu} \phi \right) \partial_\nu \Phi \right], \end{split}$$

where 
$$V_0(\phi, \phi^*) = \lambda \phi^* \phi(\phi - \phi^*)(\phi^* - \phi) + \dots$$

#### Satisfying the Sakharov Conditions

- The complex scalar potential.
- Oerivative coupling interaction.

#### 8 Reheating epoch.

# $U(1)_L$ Global Symmetry

- Identify the U(1) symmetry with L charge, where  $\phi$  has charge 2.
- *L* preserving interactions,  $\mathcal{L}_{int} = g_L \phi^* \bar{\nu}_R^c \nu_R + y_H H \bar{L} \nu_R + h.c.$

• Taking 
$$\phi$$
 in polar form,  $\ \phi = rac{1}{\sqrt{2}} \phi_{ extsf{r}} e^{i heta}$  ,

$$V(\phi_r,\theta) = \lambda \phi_r^4 \sin^2 \theta + \cdots$$

and

$$n_L = j^0 = -2\phi_r^2 \left(\dot{\theta} - \frac{\dot{\Phi}}{\Lambda}\right) \;.$$

A non-zero  $n_L$  requires driven motion in  $\dot{\theta}$  .

### Behaviour of the Inflaton

Assuming Starobinsky inflation  $(U(\Phi) \approx \frac{1}{2}\mu^2 \Phi^2)$  during reheating,

$$\ddot{\Phi} + \left(rac{2}{t}\dot{\Phi} + \Gamma\dot{\Phi}
ight) + \mu^2\Phi + rac{\lambda\phi_r^4}{\Lambda}\sin(2 heta) = 0 \; .$$

Need the inflaton (Torque) to be unaffected by  $\theta$ ,  $(\mu^2 \Phi \gg \lambda \phi_r^4/\Lambda)$ ,

$$\ddot{\Phi} + \left(\frac{2}{t} + \Gamma\right)\dot{\Phi} + \mu^2\Phi = 0.$$

When  $\Gamma \ll \mu$ , the approximate solution to this equation is

$$rac{\Phi(t)}{\Phi_i} pprox \left(rac{t_i}{t}
ight) \cos[\mu(t-t_i)]$$
 .

#### Behaviour of $\theta$

Utilising the inflaton EoM, and neglecting  $\Phi$  decay term,

$$\ddot{ heta} + (\Gamma_{ heta} + 3H) \dot{ heta} + p \sin(2 heta) = -q(t) \cos[\mu(t-t_i)] ,$$

where

$$p = \lambda \phi_r^2$$
,  $q(t) = \frac{\mu^2 \Phi_i}{\Lambda} \left( \frac{t_i}{t} \right)$ .

This is analogous to a forced pendulum where

- LHS represents acceleration, damping, and gravitation,
- RHS is a sinusoidal driving torque with amplitude q and frequency  $\mu$ .

# Possible Cases: $p \ll q(t)$

Consider a large torque  $(p \ll q(t))$ ,

$$\ddot{ heta} + 3H\dot{ heta} = rac{1}{t^2}rac{d}{dt}\left(t^2\dot{ heta}
ight) = -q(t)\cos[\mu(t-t_i)] \; ,$$

which gives,

$$\dot{ heta}(t) = rac{\dot{\Phi}}{\Lambda} \quad \Rightarrow \quad j_0 = 0$$

• L violation has vanished,  $\dot{ heta}$  oscillates around zero with  $\dot{\Phi}$  .

• Analogous to an effectively massless pendulum.

Possible Cases:  $p \gg q(t)$ 

Consider a small torque  $(p \gg q(t))$ ,

$$\ddot{\theta} + 3H\dot{\theta} + p\sin(2\theta) = 0$$

Friction term damps  $\dot{\theta}$  until  $\theta$  settles into a minima  $\Rightarrow$  no persistent non-zero  $\dot{\theta}$ .

- C and CP breaking term ignored.
- Analogous to a very massive pendulum, unaffected by input torque.

## Sweet Spot Condition and Driven Motion

We need  $p \simeq q(t) \Rightarrow L$ ,  $\mathcal{C}$  and  $\mathcal{CP}$  violating terms all contribute.

SSC: 
$$\lambda \phi_r^2 \simeq \frac{\mu^2 \Phi_i}{\Lambda} \frac{H_d}{H_i}$$

• Equivalent to  $F_d \simeq mgl$  ,

• Torque is time dependent so can only satisfy for a finite time.

Thus we want to consider,

$$\ddot{ heta} + (\Gamma_{ heta} + 3H_d)\dot{ heta} + p\sin(2 heta) = -q(t_d)\cos[\mu(t-t_i)]$$
 .

#### Phase Locked States

Reparameterise the EoM,

$$\ddot{\Theta} + rac{1}{Q}\dot{\Theta} + \sin\Theta \; = \; rac{q(t_d)}{p}\cos(\omega au) \; ,$$

- Solutions increasing monotonously in time with small modulations.
- Known as "phase-locked states" in the study of forced pendulum.

General phase-locked state solution,

$$\Theta(\tau) = \Theta_0 + n\omega\tau - \sum_{m=1}^{\infty} \alpha_m \sin(m\omega\tau - \phi_m)$$
.

### Estimation of *n* and Parameter Constraints

Consistent with our initial assumptions,

$$n\simeq \frac{2\lambda\phi_r^2}{\mu^2}$$

where n/2 = number of rotations of  $\theta$  per oscillation of  $\Phi$ .

- $\bullet$  After the SSC is violated no simultaneous violation of  $\mathcal{C},\,\mathcal{CP}$  and L ,
- Can approximate the amplitude of oscillations as,  $\sin 2\theta \approx \frac{H}{H_d}$ .

Parameter constraints (e.g.  $\Phi$  is unaffected by  $\theta$ ),

$$10^{15} \text{ GeV} > \phi_r > \mu ,$$
  

$$1 > \lambda > 5 \times 10^{-4} ,$$
  

$$310 > n > 1 .$$

#### The Generated Asymmetry and Neutrino Masses Assuming no additional entropy production,

$$\eta^{\rm reh} = \frac{n_L}{s} \approx 0.04n \times \left(\frac{\mu \phi_r^2}{T_{\rm reh}^3}\right) \left(\frac{a_d}{a_{rh}}\right)^3$$

Generated baryon asymmetry,

$$\frac{\eta}{\eta_{obs}} = \frac{T_{rh}}{2\lambda \cdot 10^8 \text{ GeV}}$$

L preserving interaction, generates a Majorana mass,

$$10^{14} \text{ GeV} > m_{\nu_R} > 10^{11} \text{ GeV}$$
 .

Via the seesaw mechanism,

$$m_
u = y_H^2 v_h^2/2m_{
u_R}$$
 .

N. D. Barrie (Kavli IPMU (WPI))

## Conclusion and Future Work

- Interplay between inflaton and scalar lepton during reheating,
- Driven motion can be modelled as a forced pendulum,
- Presence of phase-locked states,
- Asymmetry linearly dependent on the reheating temperature.
- Seesaw mechanism generates active neutrino masses.

#### Future work

- Investigation of efficiency required.
- Other cosmological implications
