Deatonomization of cluster integrable systems

Wednesday, 6 February 2019 14:00 (1 hour)

To any Newton polygon one can assign the cluster integrable system. The group G of discrete flows acts on the phase space, preserving the integrals of motion of the cluster integrable system. After deautonomization the action G leads to q-difference equations, which are equations of isomonodromic deformations of linear q-difference equations. Finally, these equations can be explicitly solved using Nekrasov functions of 5d supersymmetric gauge theory or partition functions of topological strings. The Seiberg-Witten curve for corresponding supersymmetric gauge theory and toric Calabi-Yau are constructed from the initial Newton polygon.

Based on joint works with A. Marshakov and P. Gavrylenko.
