Spontaneous Symmetry Breakdown without Massless Bosons*

PETER W. HIGGS†

Department of Physics, University of North Carolina, Chapel Hill, North Carolina

(Received 27 December 1965)

We examine a simple relativistic theory of two scalar fields, first discussed by Goldstone, in which as a result of spontaneous breakdown of U(1) symmetry one of the scalar bosons is massless, in conformity with the Goldstone theorem. When the symmetry group of the Lagrangian is extended from global to local U(1) transformations by the introduction of coupling with a vector gauge field, the Goldstone bosons becomes the longitudinal state of a massive vector boson whose transverse states are the quanta of the transverse gauge field. A perturbative treatment of the model is developed in which the major features of these phenomena are present in zero order. Transition amplitudes for decay and scattering processes are evaluated in lowest order, and it is shown that they may be obtained more directly from an equivalent Lagrangian in which the original symmetry is no longer manifest. When the system is coupled to other system is a U(1) invariant Lagrangian in the coupled continued to the coupled to the coupled to the coupled coupled to the c

A PHENOMENOLOGICAL PROFILE OF THE HIGGS BOSON

John ELLIS, Mary K. GAILLARD * and D.V. NANOPOULOS ** CERN, Geneva

Received 7 November 1975

A discussion is given of the production, decay and observability of the scalar Higgs boson H expected in gauge theories of the weak and electromagnetic interactions such as the Weinberg-Salam model. After reviewing previous experimental limits on the mass of the Higgs boson, we give a speculative cosmological argument for a small mass. If its mass is similar to that of the pion, the Higgs boson may be visible in the reactions $\pi^-p \to Hn$ or $\gamma p \to Hp$ near threshold. If its mass is $\lesssim 300$ MeV, the Higgs boson may be present in the decays of kaons with a branching ratio $O(10^{-7})$, or in the decays of one of the new par-

tiples 2.7 - 2.1 + U with a bounding actio O(10-4) If its mass is <4 CoV, the Higgs

J. Ellis et al. / Higgs boson

We should perhaps finish with an apology and a caution. We apologize to experimentalists for having no idea what is the mass of the Higgs boson, unlike the case with charm [3,4] and for not being sure of its couplings to other particles, except that they are probably all very small. For these reasons we do not want to encourage big experimental searches for the Higgs boson, but we do feel that people performing experiments vulnerable to the Higgs boson should know how it may turn up.

Higgs is such as mass of f its mass p → Hn or nt in the

VOLUME 137, NUMBER 2B Angular Correlations in Ke4 Decays and Determination of Low-Energy 7-7 Phase Shifts*

> NICOLA CABIBBO† AND ALEXANDER MAKSYMOWICZ Lawrence Radiation Laboratory, University of California, Berkeley, California (Received 1 September 1964)

The study of correlations in Ket decays can give unique information on low-energy x-x scattering. To this end we introduce a particularly simple set of correlations. We show that the measurement of these correlations at any fixed \(\pi - \pi \) c.m. energy allows one to make a model-independent determination of the difference δ₀-δ₁ between the S- and P-wave π-π phase shifts at that energy, Information about the average value of δ₀-δ₁ can be obtained from a measurement of the same correlations averaged over the energy spectrum. Measurement of the average correlations is particularly suited to the testing of any model of low-energy π-π scattering. We discuss in particular two such models: (a) the Chew-Mandelstam effective-range description of S-wave scattering and (b) the Brown-Faier σ-resonance model for the S wave. If the Chew-Mandelstam description is adequate, the suggested measurements should yield a value for the S-wave scattering length in the I=0 state. If the σ -resonance model is correct, these measurements should yield a value for the mass of the resonance.

dominated by the postulated σ resonance. Measurement of average correlations could then be used to determine the mass of this resonance.

 $\Delta \phi$

II. KINEMATICS AND CORRELATIONS

Our approach to the kinematics of the reaction $K^+ \rightarrow \pi^+\pi^-e^+\nu$ is the same as that used in analyzing resonances. We visualize this reaction as a two-body decay into a dipion of mass M ... and a dilepton of mass M... We then consider the subsequent decay of each of these two "resonances" in its own center-of-mass system.

9 The usefulness of angular correlations in the determination of δ₁—δ₁ was first recognized by E. P. Shabalin, Zh. Eksperim. i Teor. Fiz. 44, 765 (1963) [English transl.: Soviet Phys.—IETP 17, 517 (1963)]. See also erratum, Zh. Eksperim. i Teor. Fiz. 45, 2085

- systematic error: Gaussian, if measured
- theory error: not Gaussian
- profile likelihood construction: RFit [CKMFitter]

$$\begin{aligned} -2\log\mathcal{L} &= \chi^2 = \vec{\chi}_d^T \ C^{-1} \ \vec{\chi}_d \\ \chi_{d,i} &= \begin{cases} 0 & |d_i - \vec{d}_i| < \sigma_i^{\text{(theo)}} \\ \frac{|d_i - \vec{d}_i| - \sigma_i^{\text{(theo)}}}{\sigma_i^{\text{(exp)}}} & |d_i - \vec{d}_i| > \sigma_i^{\text{(theo)}} \end{cases} \end{aligned}$$

Efficient combination of errors [different from Michael's ATLAS analysis]

- Gaussian ⊗ Gaussian: half width added in quadrature Gaussian/Poisson ⊗ flat: RFit scheme
 - Gaussian ⊗ Poisson: ??
- approximate formula $\frac{1}{\log \mathcal{L}_{\text{comb}}} = \frac{1}{\log \mathcal{L}_{\text{Galuss}}} + \frac{1}{\log \mathcal{L}_{\text{Poisso}}}$
- ⇒ error bars from toy measurements

Meaning

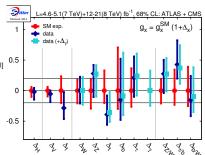

Couplings now and in the future

Now [Aspen/Moriond 2013]

- focus SM-like [secondary solutions possible]
- six couplings and ratios from data g_b from width g_g vs g_t not yet possible

[similar: Ellis etal, Djouadi etal, Strumia etal, Grojean etal]

- poor man's analyses: $\Delta_H, \Delta_V, \Delta_f$
- Tevatron H o bar b with little impact

Meaning

Meaning

TeV-scale scenarios

- fourth chiral generation excluded
- strongly interacting models retreating [Goldstone protection]
- extended Higgs sectors wide open
- no final verdict on the MSSM
- hierarchy problem worse than ever [light fundemental scalar discovered]
- ⇒ do not know

- Planck-scale extrapolation [Holthausen, Lim, Lindner]

$$\frac{d\,\lambda}{d\,\log Q^2} = \frac{1}{16\pi^2} \left[12\lambda^2 + 6\lambda\lambda_t^2 - 3\lambda_t^4 - \frac{3}{2}\lambda\left(3g_2^2 + g_1^2\right) + \frac{3}{16}\left(2g_2^4 + (g_2^2 + g_1^2)^2\right) \right]$$

- vacuum stability right at edge
- IR fixed point for λ/λ_t^2 fixing m_H^2/m_t^2 [with gravity: Shaposhnikov, Wetterich]

$$m_H = 126.3 + \frac{m_t - 171.2}{2.1} \times 4.1 - \frac{\alpha_s - 0.1176}{0.002} \times 1.5$$

- IR fixed points experimental nightmare
- ⇒ do not know

Big and small questions for the LHC and ILC

Big

- is it really the Standard Model Higgs?
- is there space for new physics outside the Higgs sector?

Small

- what are good alternative test hypotheses?
- how can we improve the couplings fit precision?
- how can we measure the bottom Yukawa?
- how can we measure the top Yukawa?
- how can we measure the Higgs self coupling?
- which backgrounds do we need to know better?
- …
