SUSY: Model-building and Phenomenology

SUSY results from the ATLAS experiment

Shimpei Yamamoto (ICEPP, Univ. of Tokyo)

December 2-4, 2013 @Kavli IPMU

Outline

Introduction

- General search strategy
- Data up to LHC long shutdown I
- Detector & basic performances
- Search programs
 - Inclusive searches for squark/gluino production
 - 3rd generation squark production
 - Electroweak gaugino/slepton production
 - Searches with odd tracks/signatures
 - RPV decays

Summary

General search strategy

- Lots of SUSY models on market (or arise every day!)
 - Dedicated analysis for each model (top-down approach) may give the best search sensitivity, but experimentalists cannot do that..
- We then adapt the bottom-up approach:
 - Identify event topologies/signatures that could be much distinctive when compared to SM and capture essential features of SUSY particle decays.
 - Develop an analysis (way to control background) for each signal topology.

 Our job in the experiment: "develop analyses to access signal event topologies that are expected to appear in all possible sparticle decays"

Data up to LHC long shutdown

- Could accumulate 21.3 fb⁻¹ of 8TeV pp collision data in 2012 thanks to increased luminosities.
- The price to pay for this is pileup:
 - ~20 pp interactions per bunch crossing.
 - Lots of effort to fully understand detector responses and better physics performances.

ATLAS detector

• General purpose detector: designed for the detection of SUSY decay products.

 Superb performance in Run-I, providing excellent reconstruction performances for electrons, muons, taus, photons, (b-)jets and MET.

Performance

- Pileup effect: severe especially for calorimeter energy measurement.
 - Electron response stability: OK
 - Bunch-integrated pileup contribution cancels thanks to bipolar pulse shape
 - Less pileup dependence on jet/MET measurement due to corrections to compensate pileup noise etc.

Triggers in 8TeV run

Signature	Offline selection	Trigger L1	selection EF	L1 Peak (kHz) L _{peak} = 7×10 ³³	EF Ave (Hz) L _{ave} = 5×10 ³³
Single leptons	Single muon p_{τ} > 25 GeV	15 GeV	24 GeV	8	45
single leptons	Single electron $p_T > 25 \text{ GeV}$	18 GeV	24 GeV	17	70
	2 muons $p_T > 6$ GeV	2 × 6(4 _{EOF}) GeV (also 2mu4 barrel only)	2 × 6 GeV	3	2
Two leptons	2 muons p_{τ} >15 GeV 2 muons p_{τ} > 20,10 GeV	2 × 10 GeV 15 GeV	2 × 13 GeV 18,8 GeV	1 8	5 8
	2 electrons, each $p_T > 15$ GeV	2 × 10 GeV	2×12 GeV	6	8
	2 taus p_{T} > 45, 30 GeV	15,11 GeV	29,20 GeV	12	12
Two photons	2 photons, each p_T > 25 GeV 2 loose photons, p_T > 40,30 GeV	2 × 10 GeV 12,16 GeV	2 × 20 GeV 35, 25 GeV	6 6	10 7
Single jet	Jet p_T > 360 GeV	75 GeV	360 GeV	2	5
E_T^{miss}	$E_T^{\text{miss}} > 120 \text{ GeV}$	40 GeV	80 GeV	2	17
Multi-jets	5 jets, each p_{τ} > 60 GeV 6 jets, each p_{τ} > 50 GeV	4×15 GeV	5 × 55 GeV 6 × 45 GeV	1	8
<i>b</i> -jets	b + 3 other jets p_{τ} > 45 GeV	4 × 15 GeV	4 × 45 GeV + <i>b</i> -tag	1	4
TOTAL				< 75	~ 400 (ave)

Primer of SUSY search

Discriminant used to distinguish signals from SM background

- Missing transverse momentum (MET): calculated based on calorimeter energies and reconstructed muons.
 - LSPs(neutralino, gravitino) escape from detection \Rightarrow large MET
- Jet multiplicity
 - Enhance squark/gluino decays, reduce multijet background
- b-jet: Flavor tagging using 3D tracking impact parameter (e.g., 60% efficiency, <1% mis-tag rate)
 - 3rd gen. squark decays, top, ...
- Transverse mass (m_T)
 - Separate from W+jets
- Scalar sum of visible objects (H_T), effective mass ($m_{eff}=H_T+MET$)
 - Large values expected when heavy particles are produced

• Contraverse mass (m_{CT}) $m_{CT}^2 = (E_T^{b_1} + E_T^{b_2})^2 - |\mathbf{p}_T^{b_1} - \mathbf{p}_T^{b_2}|^2$

- Separate from ttbar
- ••••

Primer of SUSY search

Search programs

 Again, topology-based analyses developed to cover all possible decay signatures by adopting given triggers and discriminants (previously listed).

squark/gluino production

Inclusive searches with jets+MET+X

- Can start by broad and inclusive searches in jets+MET+X final states to explore squark/gluino production.
 - Large production cross section via strong interaction
 - Excesses expected to appear in large MET & m_{eff} regions where few SM background expected.
- Very powerful analyses!
 - Can address with early data sample, statistics does not help because the cross section steeply drops when squark/gluino mass increases.
 - Performed with several signal search regions that are (nearly) orthogonal.

0-lepton + 2-6 jets + MET
0-lepton + 7-10 jets + MET Sig.
1-2 leptons + jets + MET
2-lepton + jets + MET
1-2 taus + jets + MET

MSUGRA/CMSSM exclusion: 2013 summer

• Gluino masses below ~I.3 TeV for any squark mass

Accessing the corner of parameter space

- The inclusive searches are powerful, but there could be the corners of parameter space that they cannot address..
 - Compressed mass spectrum leads to softer kinematics.

3rd gen. squark production

Stop decays

- Many possible decay modes depending on stop-LSP mass relation:
- Dedicated analyses to explore each decay/signal topology.

0-leptons + 6-jets (2 b-jets) + MET I-lepton + 4-jets (2 b-jets) + MET 2-leptons (+ 2 b-jets) + MET charm / mono-jet + MET Z(II) + 2 b-jets + MET ...

Summary: stop to t/b/c+LSP

Could extend the reach along the diagonal by adopting the ISR jet tag & charm tag techniques!

Summary: stop to b+chargino

Direct stop search summary

gaugino/slepton production

M_1 , M_2 , and μ

and μ

Decay mode/cross section determined by the order of M₁, M₂,

- In natural SUSY scenarios (Bino LSP), EW gaugino decays lead to high lepton multiplicities.
 - Dedicated analyses performed depending on the lepton multiplicity

Summary: EW gaugino production

- Constraint on NI-CI(N2) masses by searches with multilepton final states
 - Weakly constrained in the case that gauginos decay via gauge bosons

Wino-LSP case

- Wino-LSP scenarios (AMSB, PGM,...) predicts the massdegenerate C1 that could have a significant lifetime.
 - Decaying C1 could be reconstructed as a "high-pT disappearing track"
 - Explored in the events having ISR jet + disappearing track

Slepton production

Searches with odd tracks/ signatures

Odd signatures

Stopped R-hadron

- Gluino_could be meta-stable (split-SUSY) and form Rhadrons, can get stuck in the calorimeter and decay much later.
- Look for energetic jets via gluino decays in empty bunches.

Stopped R-hadron

Stopped R-hadron

- Gluino_could be meta-stable (split-SUSY) and form Rhadrons, can get stuck in the calorimeter and decay much later.
- Look for energetic jets via gluino decays in empty bunches.

Long-lived stau

• In GMSB, signal topology characterized by sparticle-type of NLSP.

- GMSB staus could have a significant lifetime and be observed as heavy muons.
- Mass can be reconstructed and used as the discriminant:

Displaced photon

- Neutralino NSLP could a significant lifetime (GMSB), then decays to gravitino+photon.
- Use timing and shower direction to distinguish photons from displaced decays.

Displaced vertex

• Displaced vertices having a large mass & large track multiplicity could arise in:

- GMSB: long-lived NLSP neutralino decay into Z/h + graviton
- GMSB: long-lived stau that decays in the inner detector
- Split-SUSY: long-lived gluino decays
- Provide background-free searches, no candidate events observed yet..
- At the moment, results interpreted in displaced neutralino decays via RPV coupling (mentioned later).

RPV signature

– RPV terms are allowed in the superpotential:

$$W = W_{MSSM} + \underline{\lambda_{ijk}L_iL_j\bar{E}_k + \lambda'_{ijk}L_iQ_j\bar{D}_k + \kappa_iL_iH_u} + \lambda''_{ijk}\bar{U}_i\bar{D}_j\bar{D}_k$$

Lepton number violating

Baryon number violating

- All terms cannot appear simultaneously, protons become unstable...
- Part of them need not to be zero, leading to variety of signatures.
- LSP could decay..
- Assume that λ has non-zero value >> large lepton multiplicity
- Assume that λ ' has non-zero value >> neutralino LSP could have a significant lifetime when $\lambda' << 10^{-5}$ (decay width proportional to $(\lambda')^2$)

$$LQ\bar{D}(\lambda'): \ \tilde{\chi}_1^0 \to \begin{pmatrix} e, \mu, \tau \\ \nu \end{pmatrix} + 2 \text{ jets}$$

 Assume that λ" has non-zero value >> neutralino could hadronically decay (into 3 quarks)

Large jet multiplicity (w/o MET)

- Hadronic RPV decay of LSP (to 3 quarks) leads to large jet multiplicity + diluted MET.
- Analysis carried out by requiring ≥6 and ≥7 jets with and without b-jet requirements

Searches for all possible SUSY decays... may complete the job for 8TeV data hopefully this winter.

Summary

- Nothing found yet in 8TeV pp collisions.. but still at the beginning of a long SUSY search program at the LHC energy frontier.
 - The colored sparticle mass reach significantly improves (up to ~3TeV) with increased beam energies.
 - 3rd. gen squarks?? The allowed parameter space has been squeezed, but there's still room that could not be accessed.
 - The sensitivity to EW production still limited by statistics. Could be addressed down to O(0.01)fb.
 - Have developed a number of new analyses that utilize ISR/soft lepton tagging and exotic tracks to cover "holes" of general/traditional searches.
 - Have nearly completed out job for 8TeV data and many search tools in hand to address all possible decays.
- LHC resumes operation in 2015 with the designed collision energy.
 - What comes in next years??
