

Introduction

Data from The HI Nearby Galaxy Survey (THINGS), Low Surface Brightness (LSB) galaxies, Galaxy clusters:

Anomaly:

* Cross section is dependent on velocity

* Can fit galaxy data from small scale to large scale

* Cold Dark Matter model is collisionless

* Easy computation of relic density

Model with a dark photon and a dark fermion

Stueckelberg U(1) extension to the Standard Model:

$$\mathcal{L} \supset -\frac{1}{4} C^{\mu\nu} C_{\mu\nu} - g_X \bar{D} \gamma^{\mu} D C_{\mu} - m_D \bar{D} D -\frac{\delta}{2} C^{\mu\nu} B_{\mu\nu} - \frac{1}{2} (M_1 C_{\mu} + M_2 B_{\mu} + \partial_{\mu} \sigma)^2,$$

- * C_{μ} , B_{μ} : gauge field of $U(1)_X$ and $U(1)_Y$
- * D: Dirac fermion, only charged under $U(1)_X$
- * δ : kinetic mixing parameter
- * M_1, M_2 : Stueckelberg masses.
- * σ : axion field which gives mass to C_{μ}

Mass eigenstates: the photon (γ) , the Z boson, and massive γ' .

Cosmologically Consistent Self-interacting Dark Matter and Small-scale Galaxy Anomalies

Evolution of two temperature universe

In our model, only the total entropy is conserved, include visible sector:

$$\frac{d}{dt}(sR^3) = 0$$

where $s = s_h + s_v$.

$$s = \frac{2\pi^2}{45} \left(h_{\text{eff}}^h T_h^{\ 3} + h_{\text{eff}}^v T^3 \right), \qquad (2)$$

The Hubble parameter also depends on both T and T_h as can be seen from the Friedman equation,

$$H^2 = \frac{8\pi G_N}{3} (\rho_v(\boldsymbol{T}) + \rho_h(\boldsymbol{T_h})), \tag{3}$$

$$\frac{dn_D}{dt} + 3Hn_D = \left[\langle \sigma v \rangle_{i\bar{i} \to D\bar{D}} (T) n_i^{\text{eq}} (T)^2 - \langle \sigma v \rangle_{D\bar{D} \to \gamma' \gamma'} (T_h) n_D (T_h)^2 + \langle \sigma v \rangle_{\gamma' \gamma' \to D\bar{D}} (T_h) n_{\gamma'} (T_h)^2 \right].$$
(4)

$$\frac{dn_{\gamma'}}{dt} + 3Hn_{\gamma'} = \left[\langle \sigma v \rangle_{D\bar{D} \to \gamma'\gamma'} (T_h) n_D(T_h)^2 - \langle \sigma v \rangle_{\gamma'\gamma' \to D\bar{D}} (T_h) n_{\gamma'} (T_h)^2 + \langle \sigma v \rangle_{i\bar{i} \to \gamma'} (T) n_i^{\text{eq}} (T)^2 - \langle \Gamma_{\gamma' \to i\bar{i}} (T_h) \rangle n_{\gamma'} (T_h) \right].$$
(5)

$$\frac{d\eta}{dT_h} = -\frac{\eta}{T_h} + \frac{\zeta\rho_v + \rho_h(\zeta - \zeta_h) + j_h/(4H)}{\zeta_h\rho_h - j_h/(4H)} \frac{\frac{d\rho_h}{dT_h}}{T_h \frac{d\rho_v}{dT}},\tag{6}$$

where $T = \eta T_h$, $\zeta = \frac{3}{4}(1 + p/\rho)$. Here $\zeta = 1$ is for the radiation dominated era and $\zeta = 3/4$ for the matter dominated universe. j_h is defined by

$$\frac{d\rho_h}{dt} + 3H(\rho_h + p_h) = j_h,\tag{7}$$

• Left side: Evolution of $\xi = T_h/T$ as a function of T for different initial conditions. Right side: Showing the evolution of the dark sector

Evolution history:

- * D, γ' is produced via freeze-in
- * D becomes abundant, $D\bar{D} \leftrightarrow \gamma' \gamma'$ becomes important
- * Freeze out in dark sector. D decouples from γ'
- * $i\bar{i} \rightarrow \gamma'$ remains efficient, causes increase in γ'
- * γ' decays before BBN

* Left side: Galaxy fit of our model constraining $m_{\gamma'} = (1-5)$ MeV, $m_D = (1-4)$ GeV * Right side: Experimental constraints from CHARM, E137, DarkSide-50 etc.

* The SIDM model with a hidden sector dark fermion and a dark photon with mass ranges

$$m_{\gamma'} = (1$$

fits data on σv from galaxy scales to galaxy clusters.

- * All relevant constraints on $m_{\gamma'}$, m_D , δ are satisfied.

Galaxy fit and experimental constraints

Benchmarks

Conclusion

(1-5) MeV, $m_D = (1-4)$ GeV

* We developed a new formalism solving Boltzmann equations with two temperatures.

* The velocity dependence of the cross sections within this model points to the existence of a dark fifth force and thus further data will help confirm the existence of such a force.
