

# **A semi-analytic model of self-interacting dark matter substructures**

**Based on Shirasaki, Okamoto, Ando (2022) MNRAS, 516, 3**

**Masato Shirasaki (National Astro. Obs. Japan, Institute of Statistical Mathematics)**

**March 8, 2023 "What is dark matter? - Comprehensive study of the huge discovery space in dark matter"**

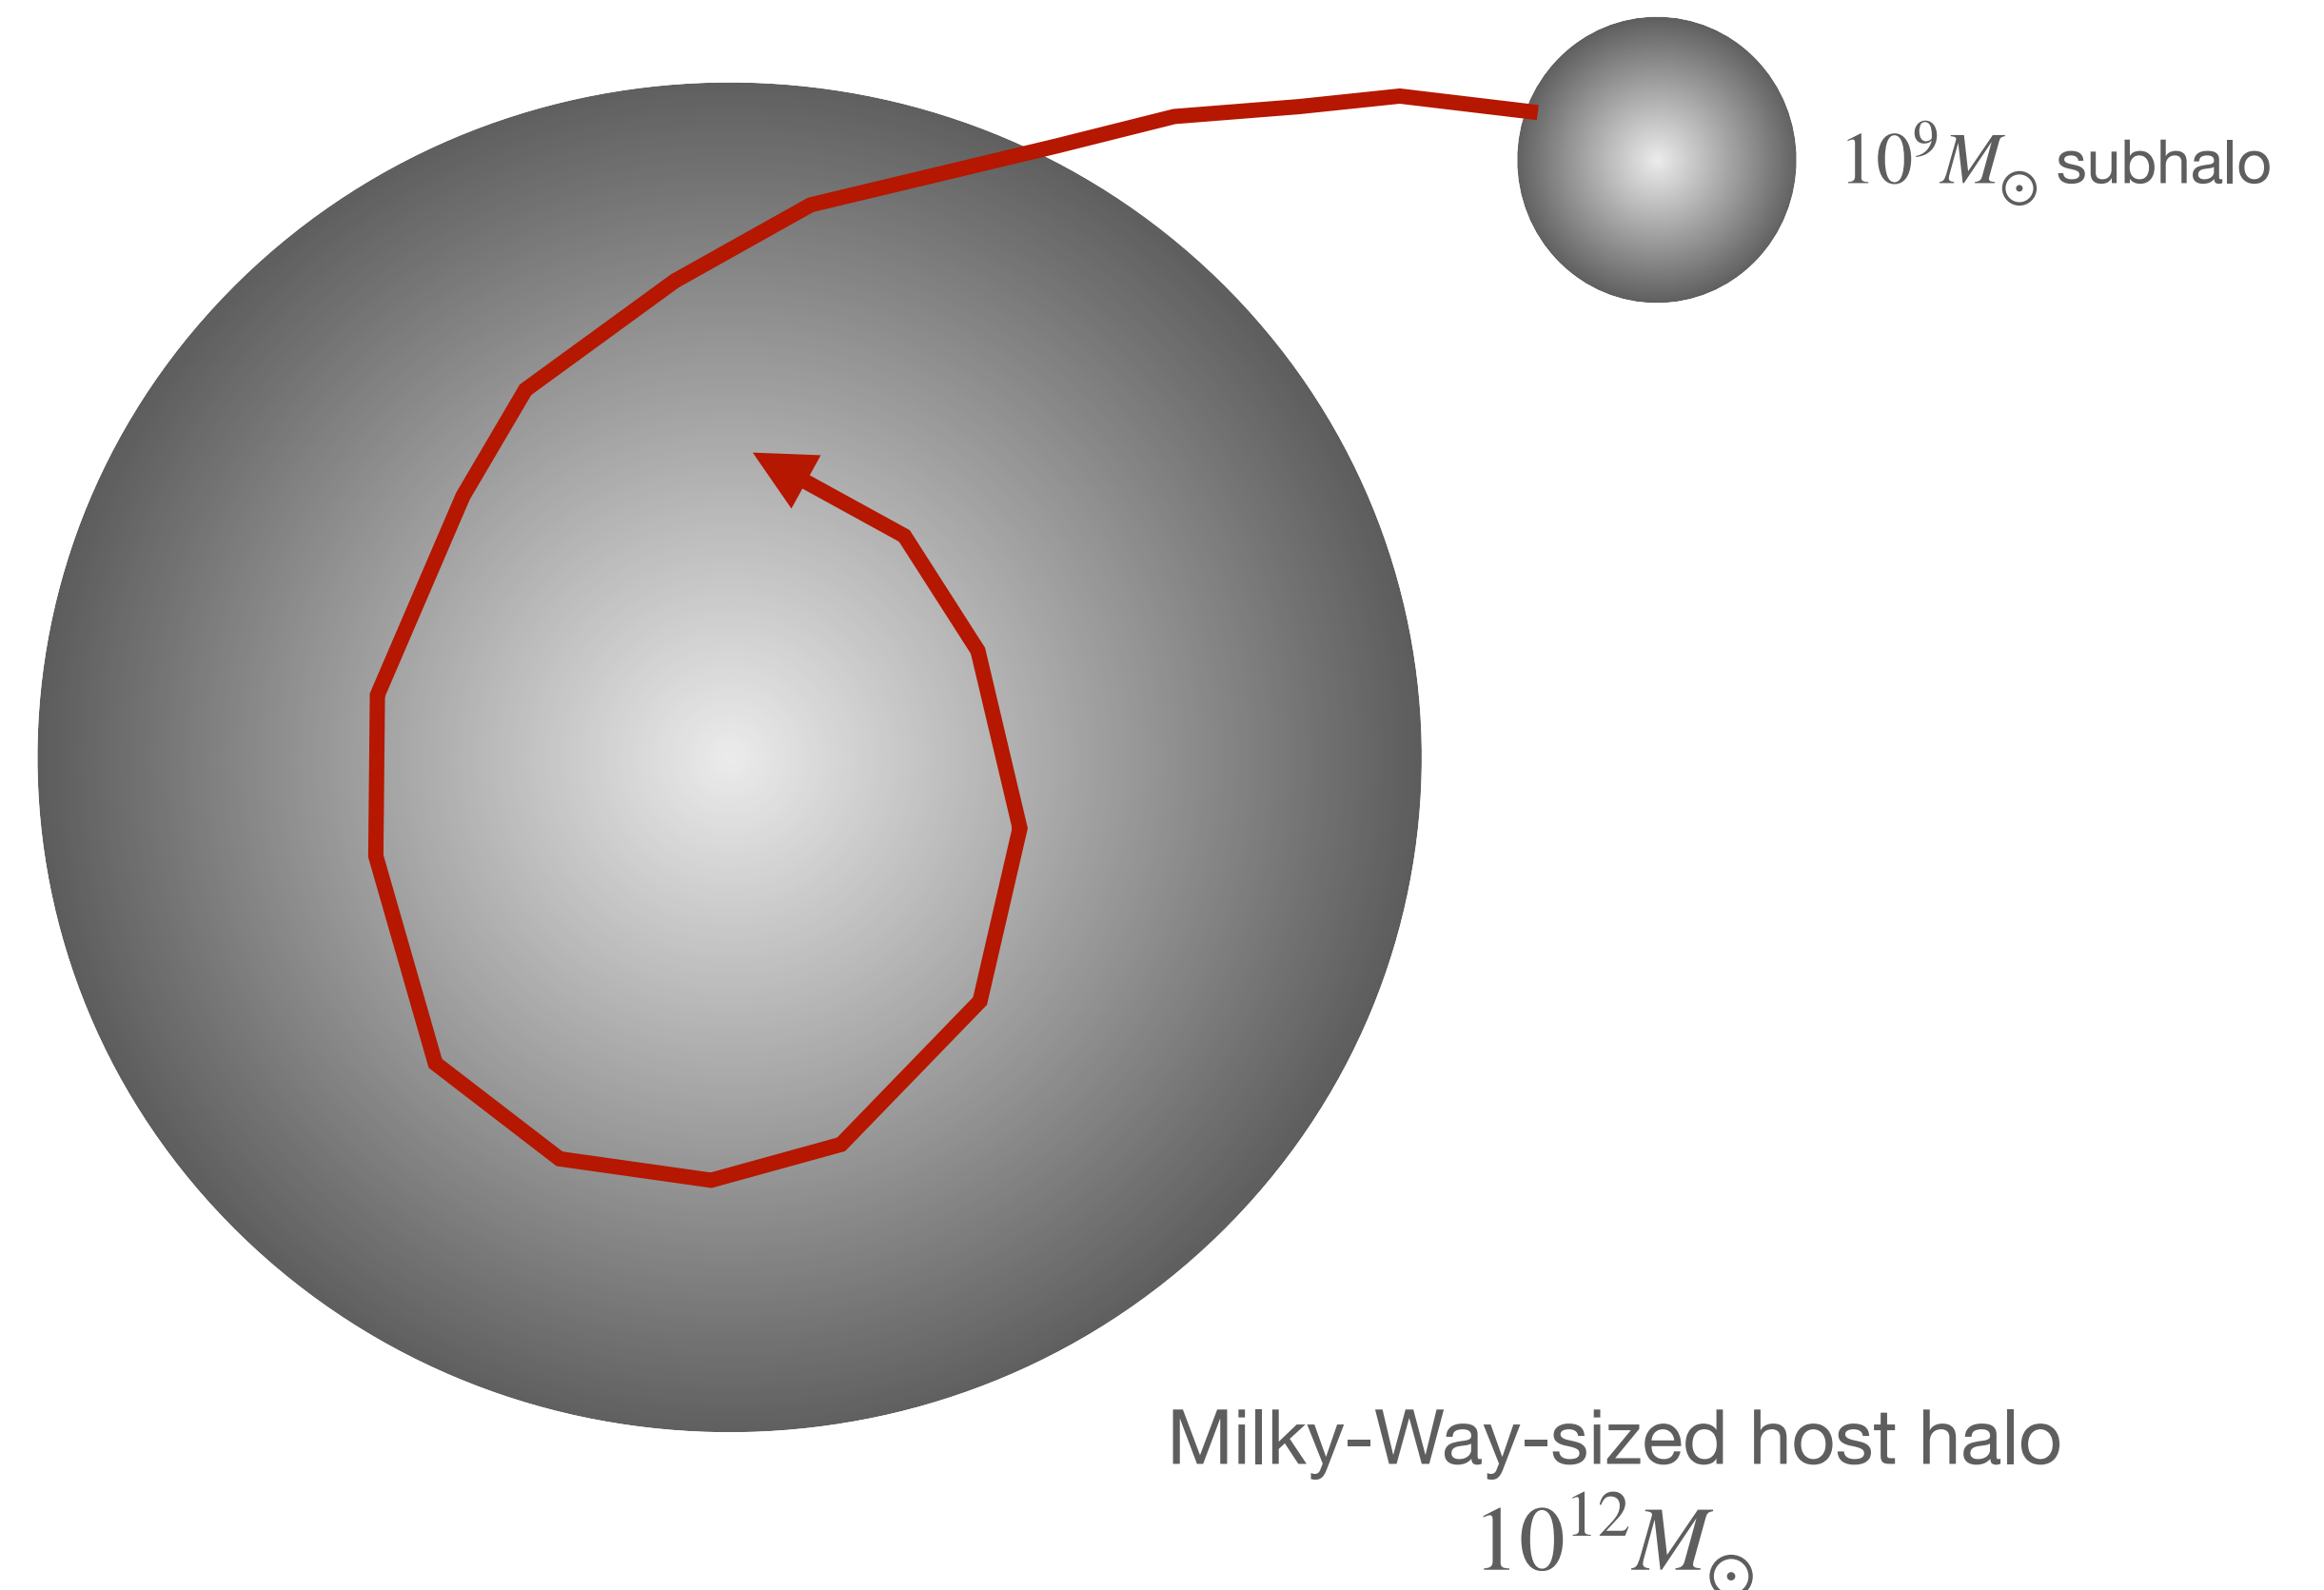

# Self-interacting dark matter (SIDM)

- Self-interacting dark matter particles with their scattering cross section of  $\sigma/m \sim O(1) \text{ cm}^2/\text{g}$  can be a good candidate for cosmic dark matter
  - A typical mean free path can be  $\sim 1$  Mpc in a galaxy if the SIDM particle mass is set to  $\sim 1$  GeV (e.g. Spergel & Steinhardt 2000)
  - Any SIDM signatures may be found in small scale structures on scales of  $< 1$  Mpc
- In practice, MW satellites are the best target to examine the nature of dark matter because they are a DM-dominated system
- Let us develop a model of SIDM subhalos with the help of simulation data.

# Semi-analytic model of SIDM subhaloes

## Calibration with ideal N-body simulations of minor mergers

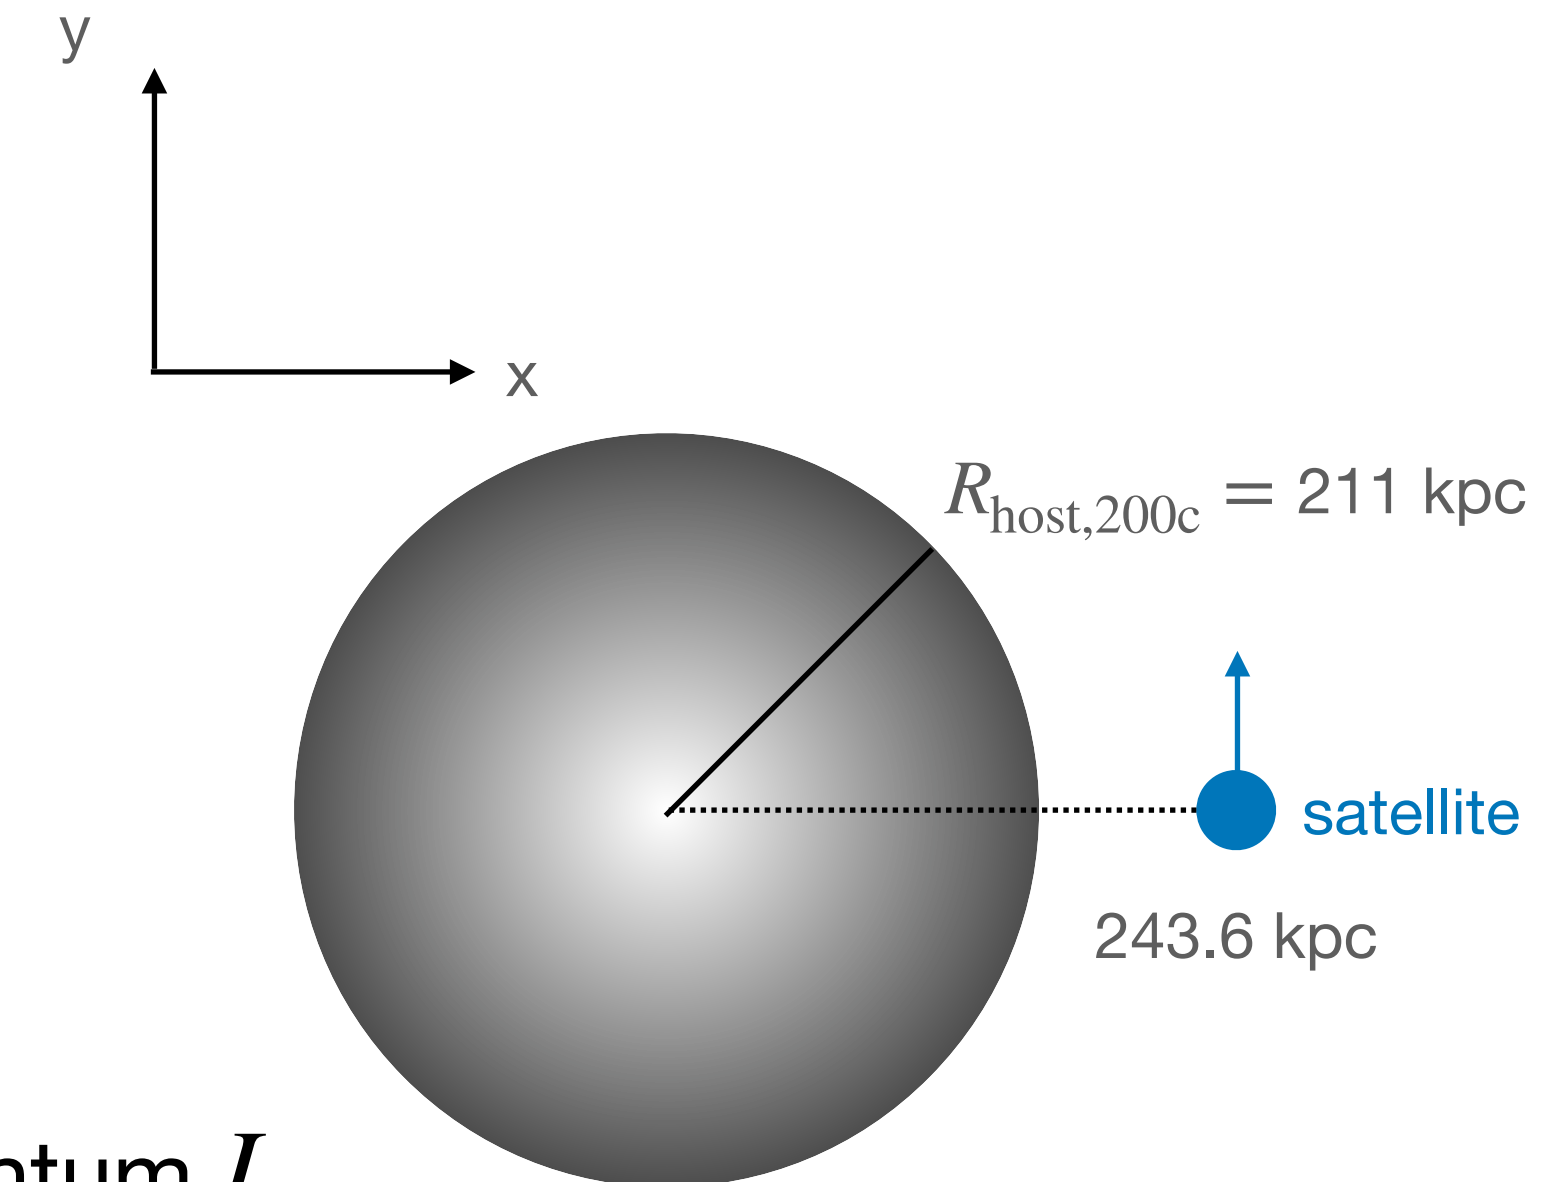

- Testing self-interactions of DM particles would require a precise modeling of
  - thermalization of SIDM halo/subhalo
  - Tidal stripping / Ram pressure
- Develop a semi-analytic model of infalling subhalos to a MW-sized halo and calibrate it with (isolated) N-body sims

# Isolated N-body halos

## Initial condition in our simulations

- Host: NFW halo ( $M_{200c} = 10^{12} M_{\odot}$ ,  $c = 10$ ,  $r_s = 21.1$  kpc)
- Satellite: NFW halo ( $M_{200c} = 10^9 M_{\odot}$ ,  $c = 6$ ,  $r_s = 1.68$  kpc)
- MAGI: Generator of spherical N-body halos in dynamical equilibrium
  - <https://bitbucket.org/ymiki/magi/src/master/>
  - No disc components for now
- Set the initial condition of the satellite with its energy  $E$  and angular momentum  $L$

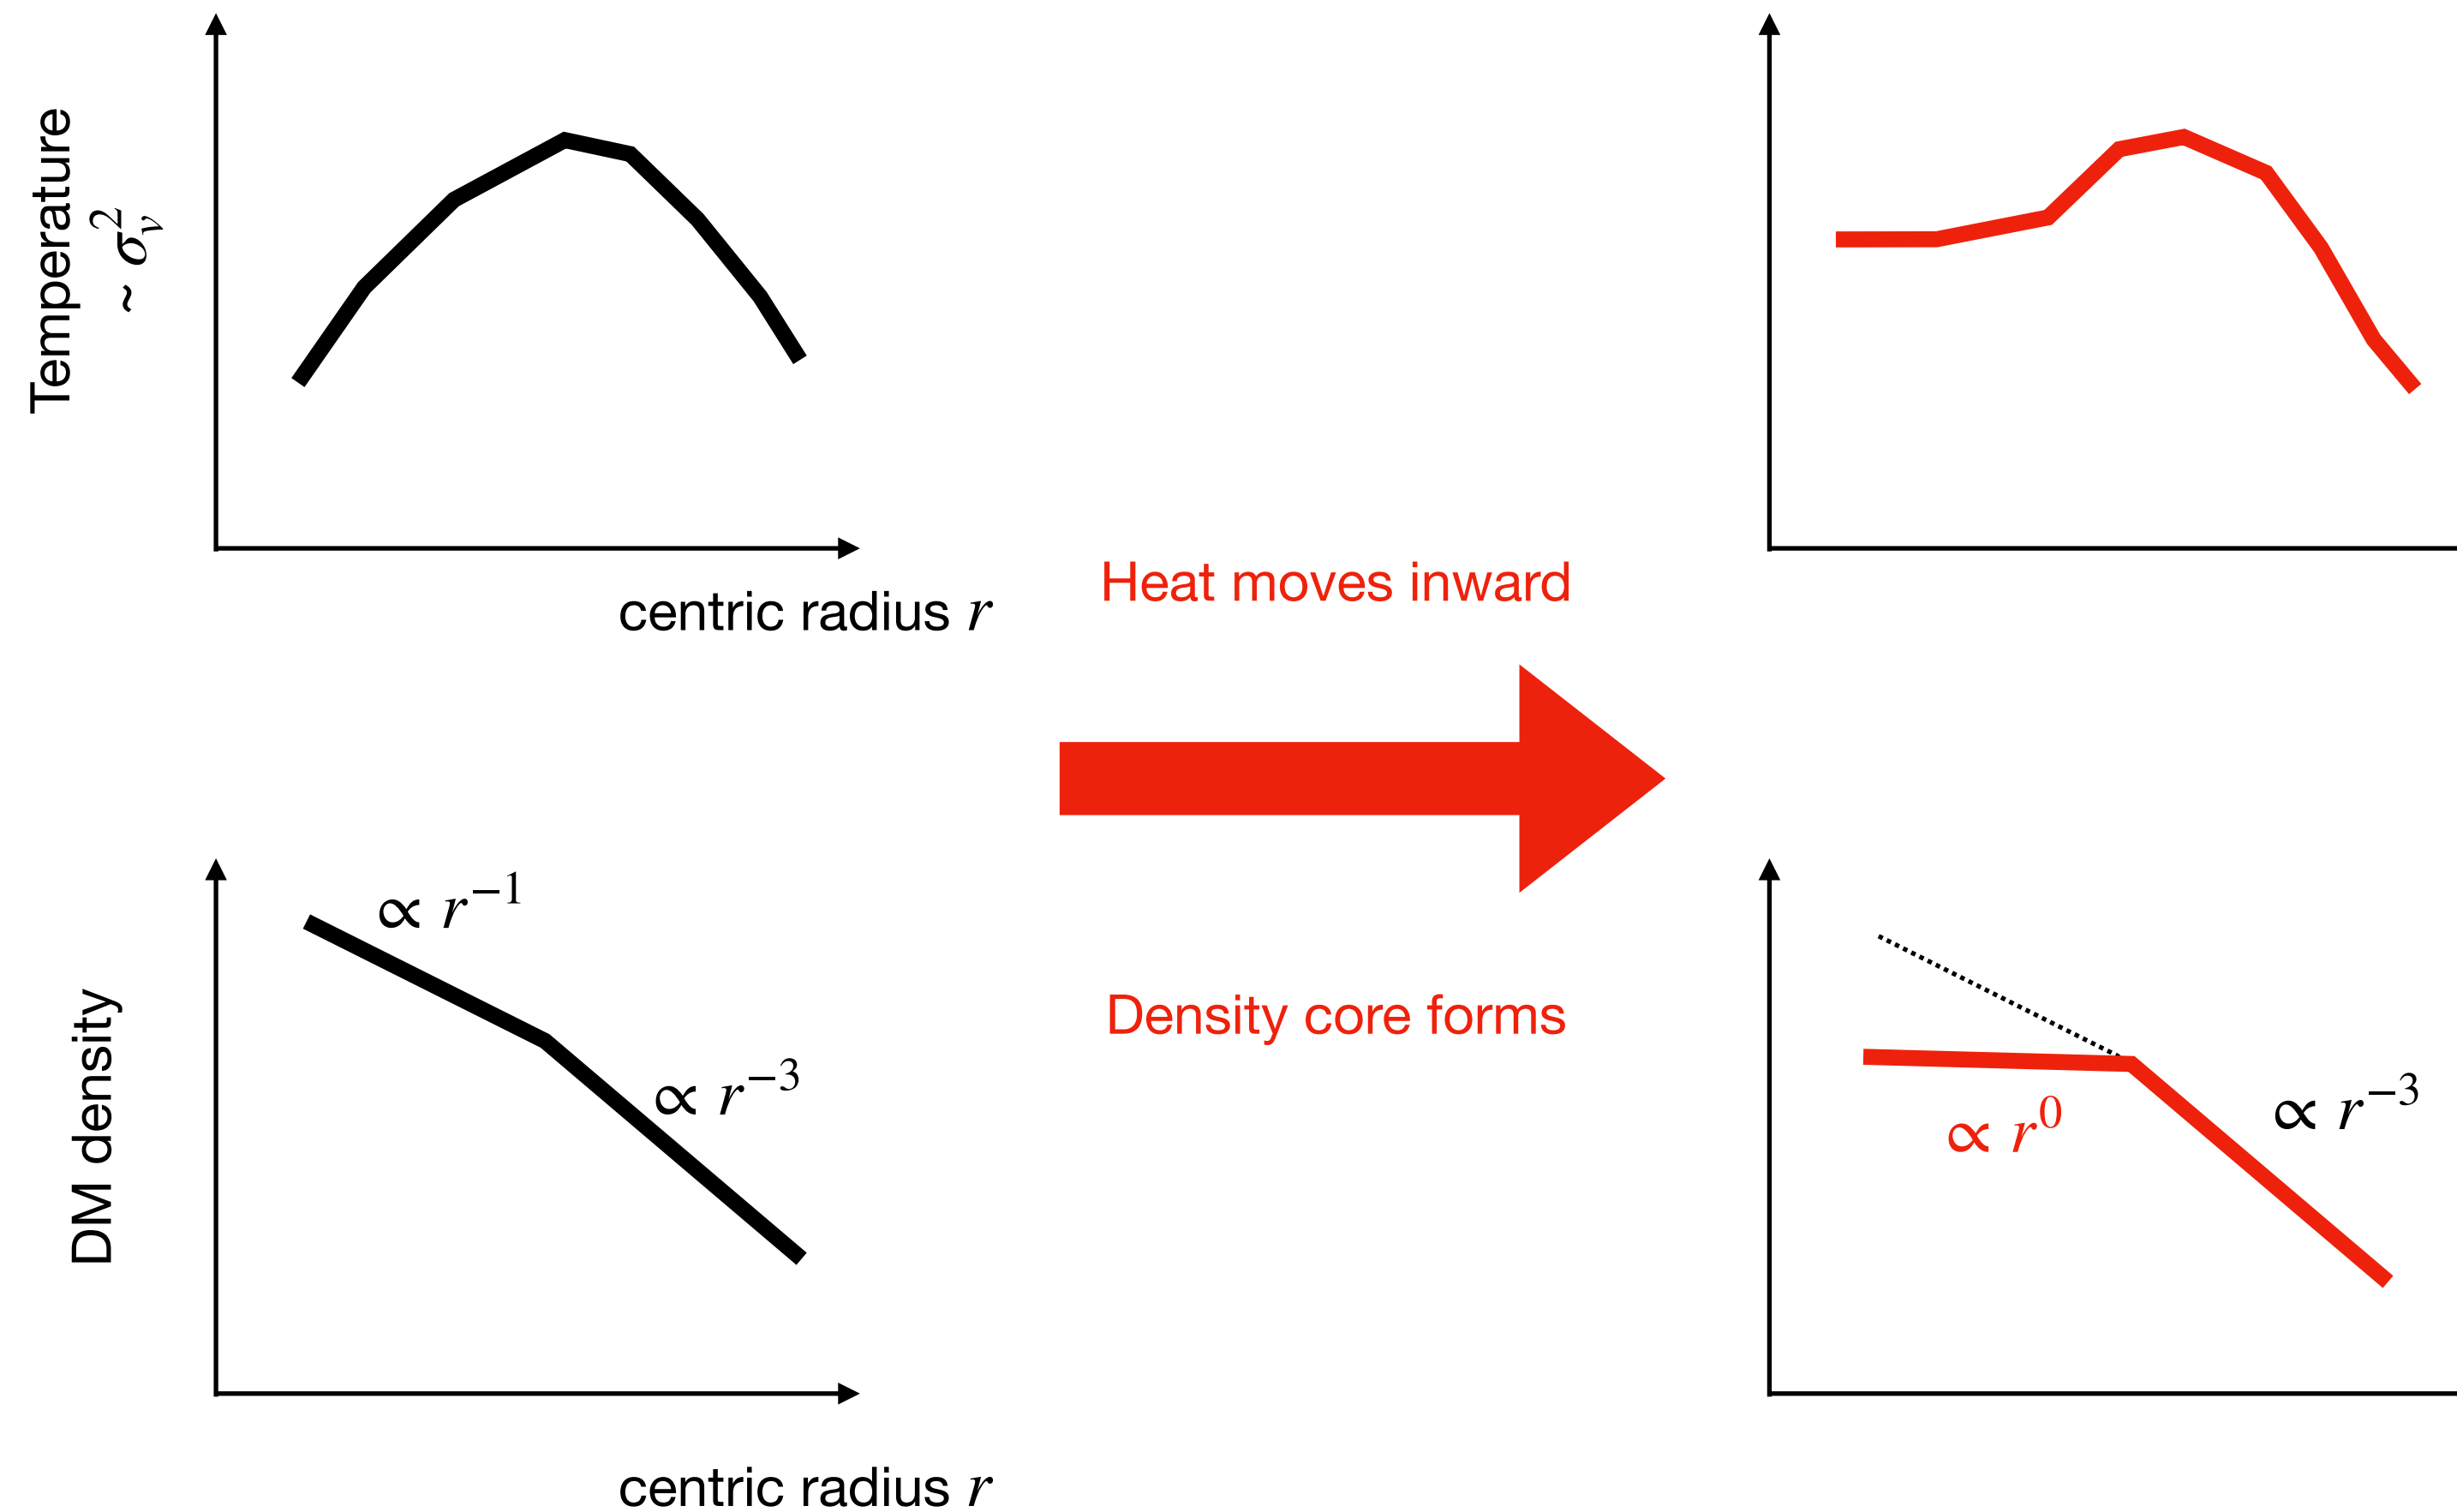

- $E = \frac{1}{2}V_c^2 + \Phi_{\text{NFW-host}}(R_c)$ ,  $L = \eta R_c V_c$  where  $V_c = (GM_{\text{host}}/R_c)^{1/2}$

- $x_c = R_c/R_{\text{host},200c} = 0.5$ ,  $\eta = 0.6 \rightarrow$  apocenter = 243.6 kpc

# Simulation

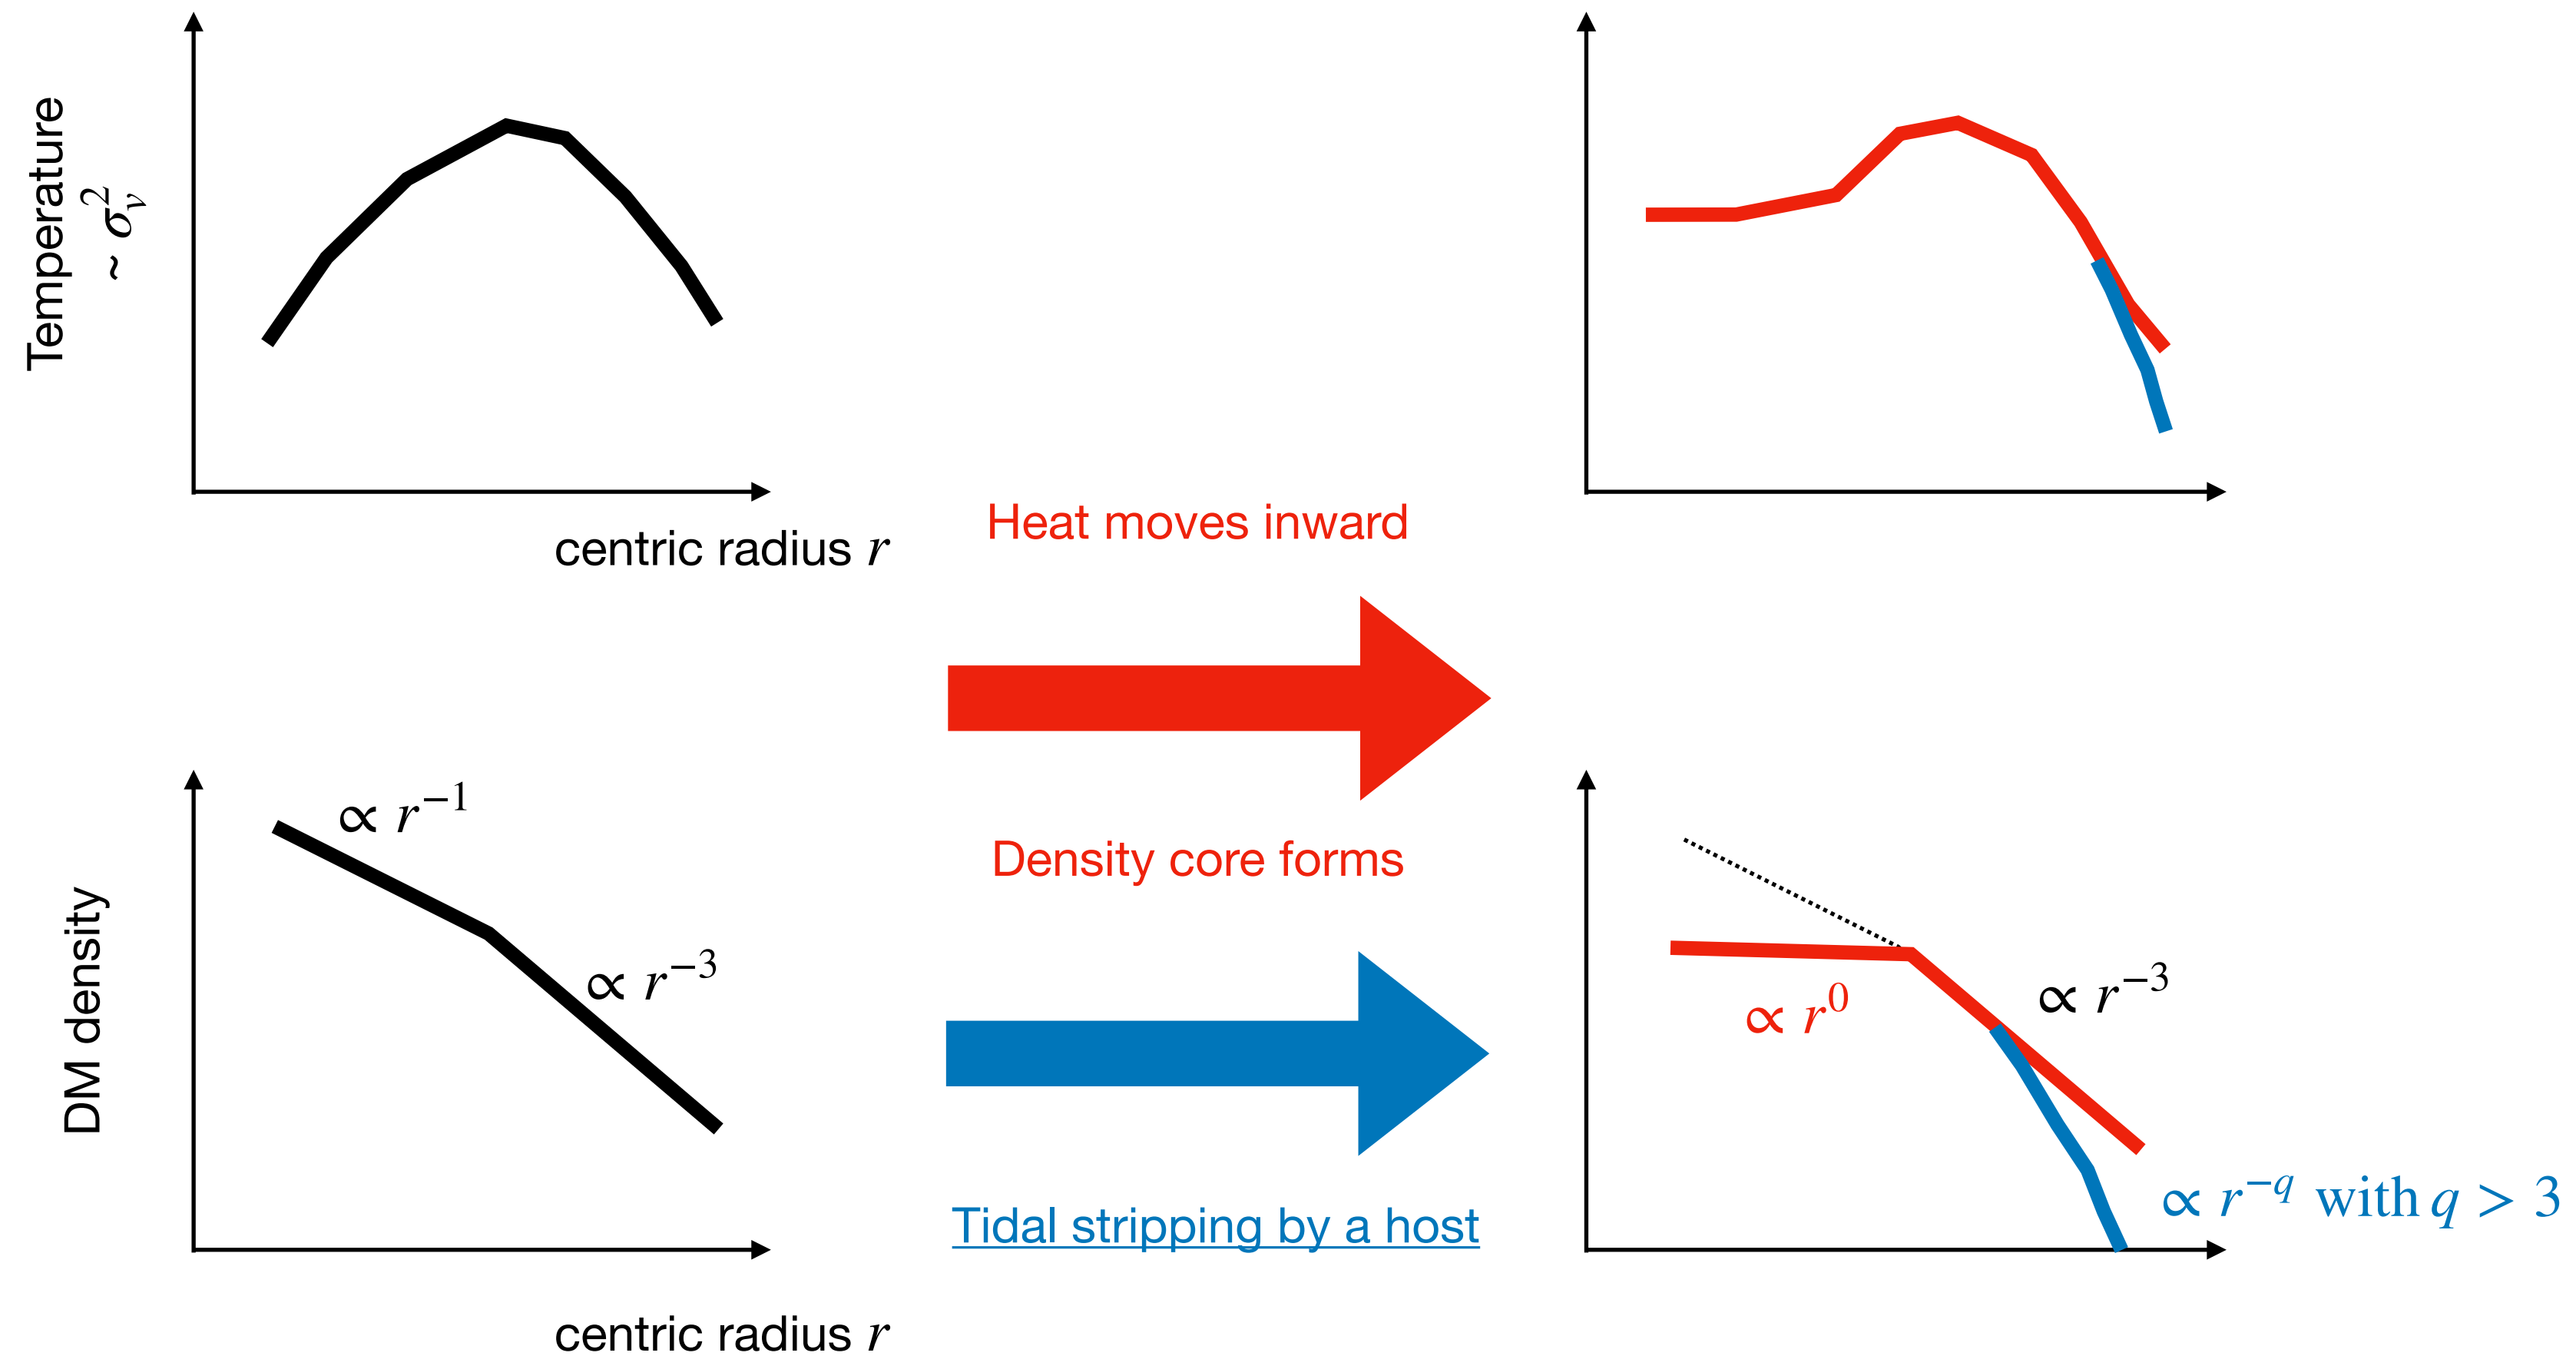

- Set the number of N-body particles to  $(N_{\text{host}}, N_{\text{sat}}) = (10^7, 10^4)$
- N-body simulation code : GIZMO+ SIDM (Hopkins 2015)
- velocity independent, isotropic scattering with  $\sigma/m$  ( $\text{cm}^2/\text{g}$ ) = 0,1,3
- Softening length =  $0.05 (N_{\text{sat}}/10^5)^{-1/3} r_{\text{s,sub}}$  (van den Bosch and Ogiya 2018)
- Maximum time step = 0.03 Gyr  $\sim$  1% of the dynamical time for a MW-like halo
- 100 snapshots with the equal-space time interval until  $t < 10$  Gyr
- Confirmed that our simulations provide converged results of subhalo profiles at  $r > 0.3$  kpc (equivalent to  $r/r_{\text{s,sub}} > 0.2$ )

# A schematic picture of time evolution of SIDM haloes

Initial state is assumed to be NFW

# A schematic picture of time evolution of SIDM subhaloes

Initial state is assumed to be NFW

# A brief summary of our model

## Gravothermal fluid model (e.g. Balberg+2002)

Host halo density  
 $\rho_h(r, t)$

Mass conservation  $dM/dr = 4\pi r^2 \rho_h(r)$

Hydrostatic equilibrium  $d(\rho \sigma_v^2)/dr = -GM\rho/r^2$

Heat Flux =  $-\kappa (m/k_B) \partial \sigma_v^2 / \partial r$  re-arranges  $\rho_h$  and  $\sigma_v$

$\rho_h(r, t + \Delta t)$

### Subhalo

Density  
 $\rho_{\text{sub}}(r, t)$

Bound Mass  
 $M_{\text{sub}}(t)$

Position & Velocity  
 $\mathbf{x}_{\text{sub}}(t), \mathbf{v}_{\text{sub}}(t)$

### CDM-like tidal evolution proposed in Green & van den Bosch (2019)

#### Gravothermal fluid model (e.g. Balberg+2002)

$\dot{M}_{\text{sub}} = (\text{Tidal stripping}) + (\text{Ram pressure evaporation})$

Analytic model in Chandrasekhar 1943

Analytic model in Kummer+2018

$\ddot{\mathbf{x}}_{\text{sub}} = -\nabla \Phi_h + (\text{Dynamical Friction}) + (\text{Ram Pressure Deceleration})$

Density  
 $\rho_{\text{sub}}(r, t + \Delta t)$

Bound Mass  
 $M_{\text{sub}}(t + \Delta t)$

Position & Velocity  
 $\mathbf{x}_{\text{sub}}(t + \Delta t), \mathbf{v}_{\text{sub}}(t + \Delta t)$

Note: We ignore possible changes of subhalo density profiles due to ram pressure effects

# Test 1: CDM-like tidal stripping model can work or not

- Green and van den Bosch (2019) have found that the tidal stripping effect in CDM subhaloes can be expressed as

- $\rho_{\text{sat}}(r, t) = H_{\text{GB19}}(r, f_b(t)) \rho_{\text{NFW}}(r)$

Mass fraction of subhaloes at t

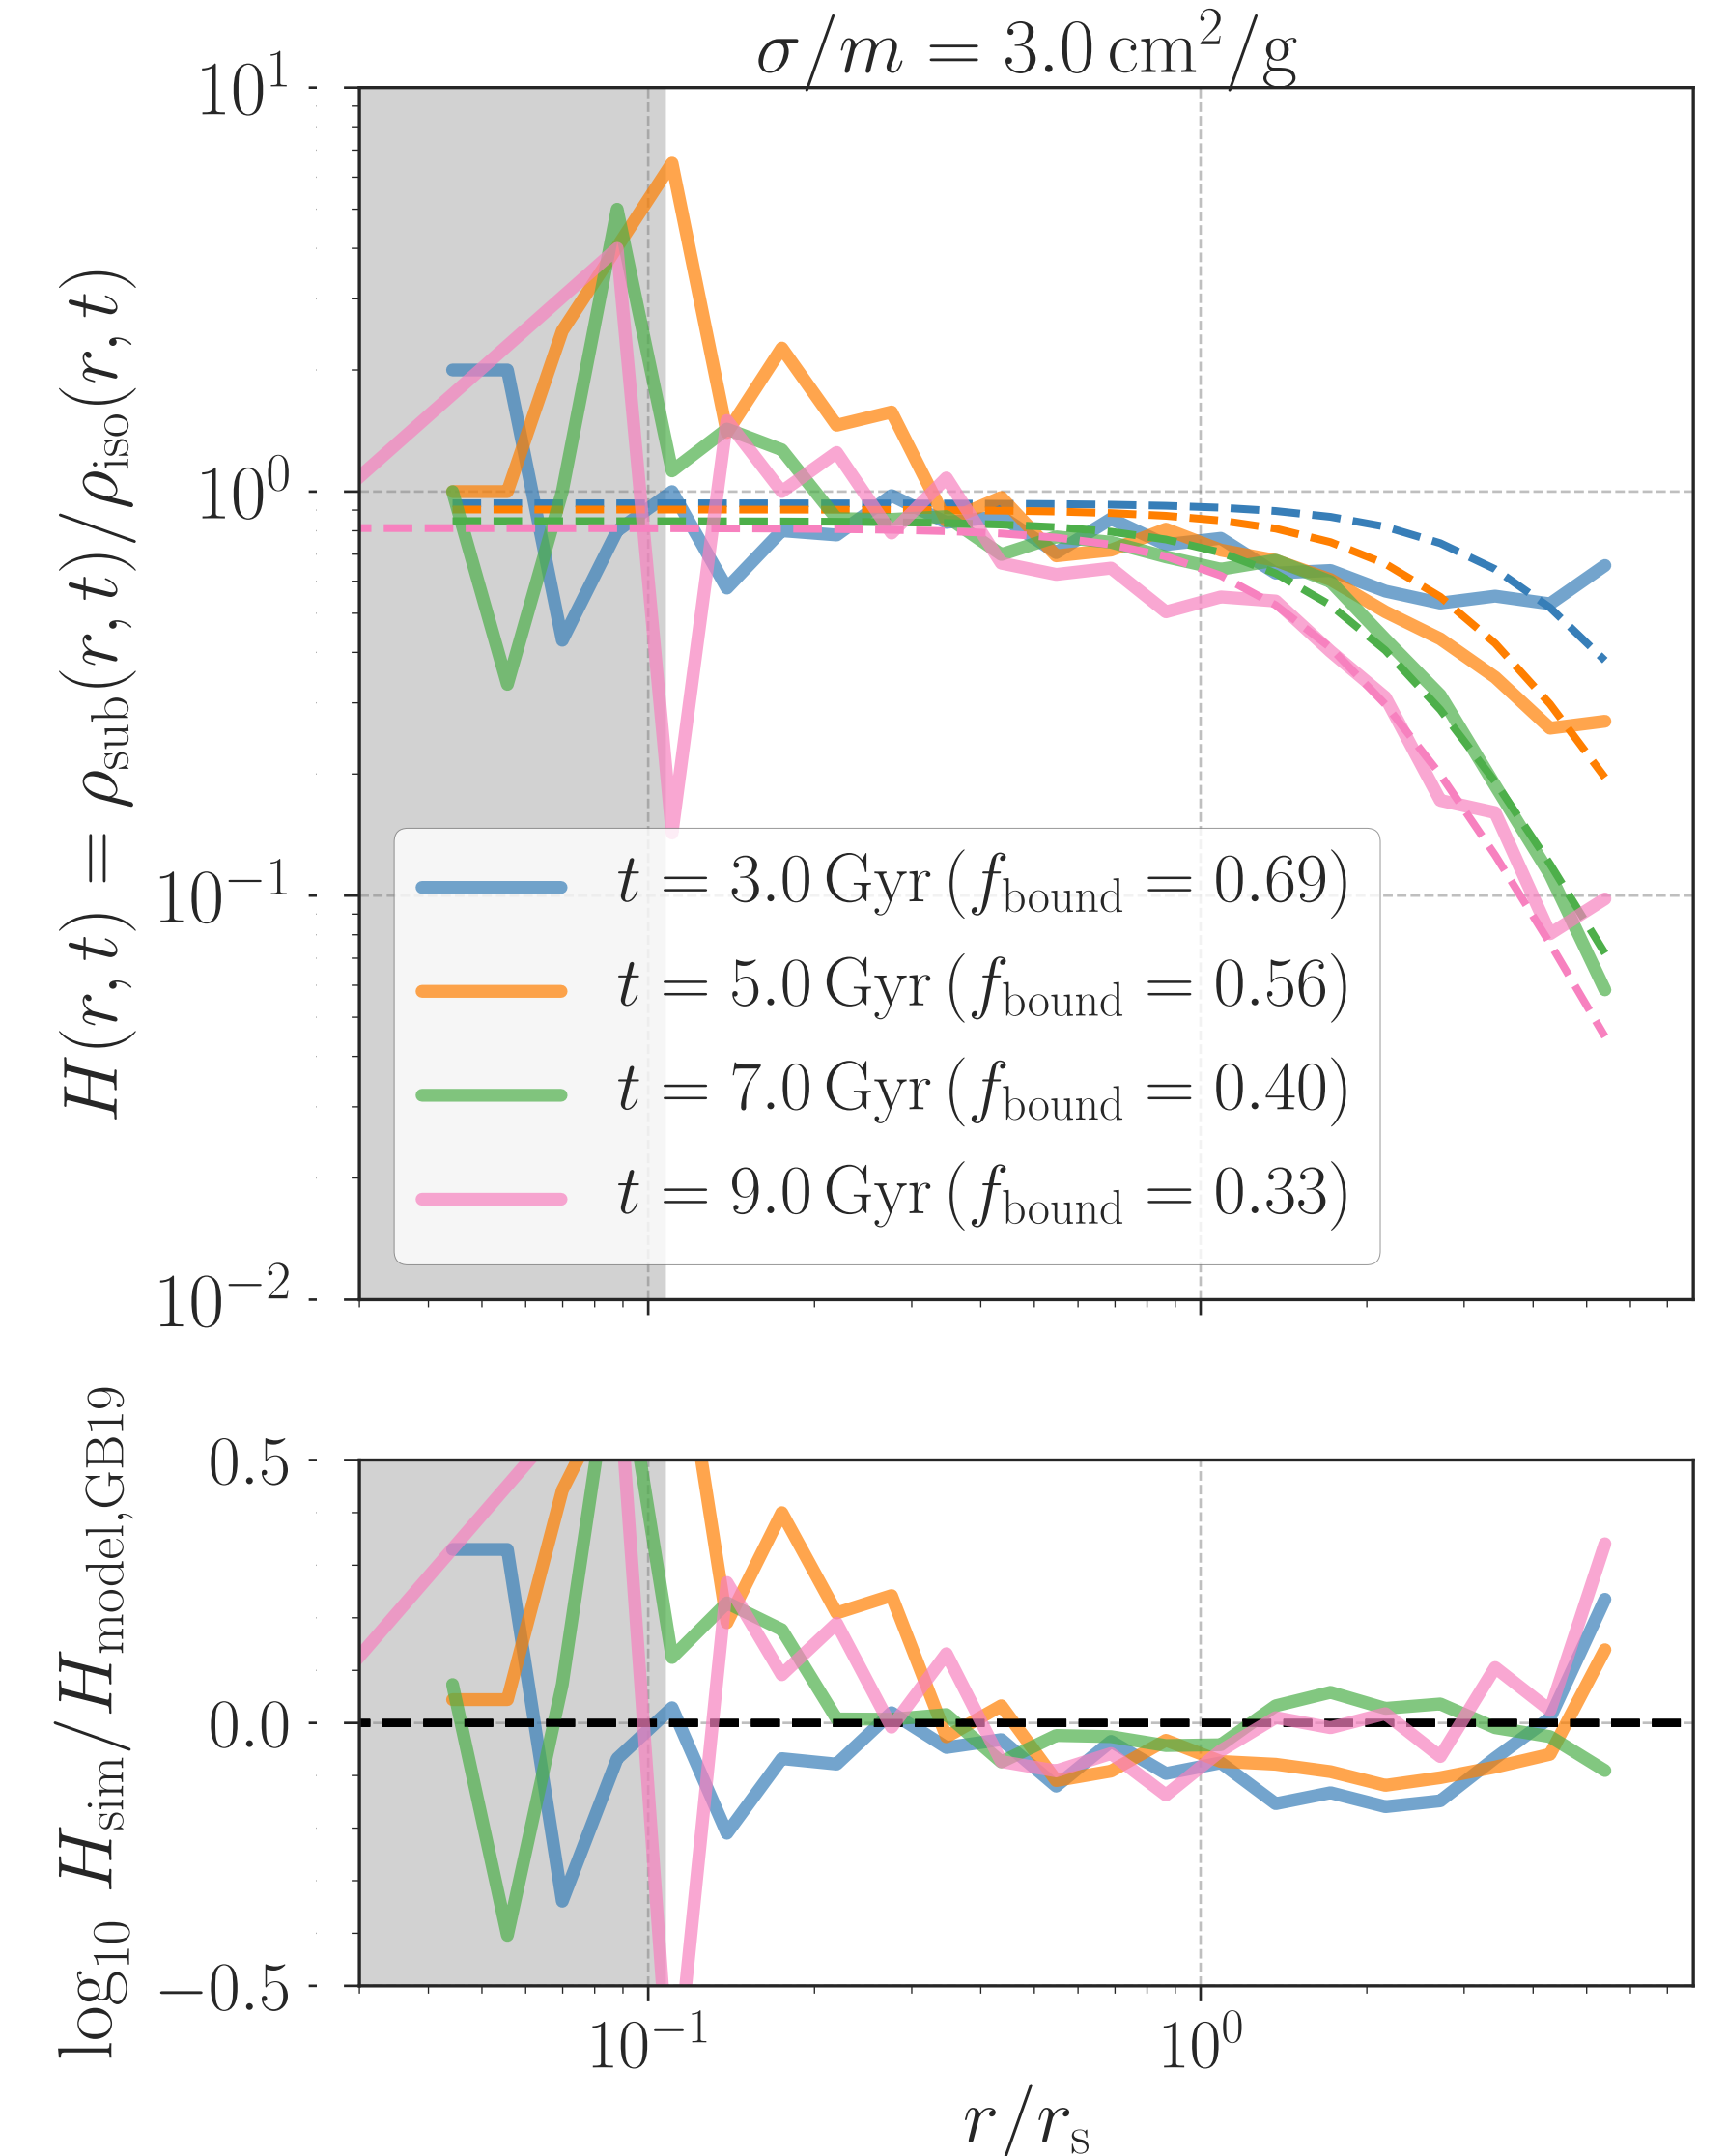

- In the SIDM case, we naively expect that

- $\rho_{\text{SIDM,sat}}(r, t) = H_{\text{GB19}}(r, f_b(t)) \rho_{\text{SIDM,iso}}(r, t)$

- We evolved isolated haloes with the same mass as the subhalo at initial states and then compute

- $H_{\text{sim}}(r, t) = \frac{\rho_{\text{sat}}(r, t)}{\rho_{\text{iso}}(r, t)}$

- Confirmed  $H_{\text{sim}} \simeq H_{\text{GB19}}$  in our simulations

# Test 2: Subhalo mass loss rate in SIDM

- The mass loss rate by tidal stripping effects is commonly modeled as

$$\frac{dM_{\text{sub}}}{dt} = -\alpha \frac{M_{\text{sub}}(r > r_t, t)}{\tau_{\text{dyn}}}$$

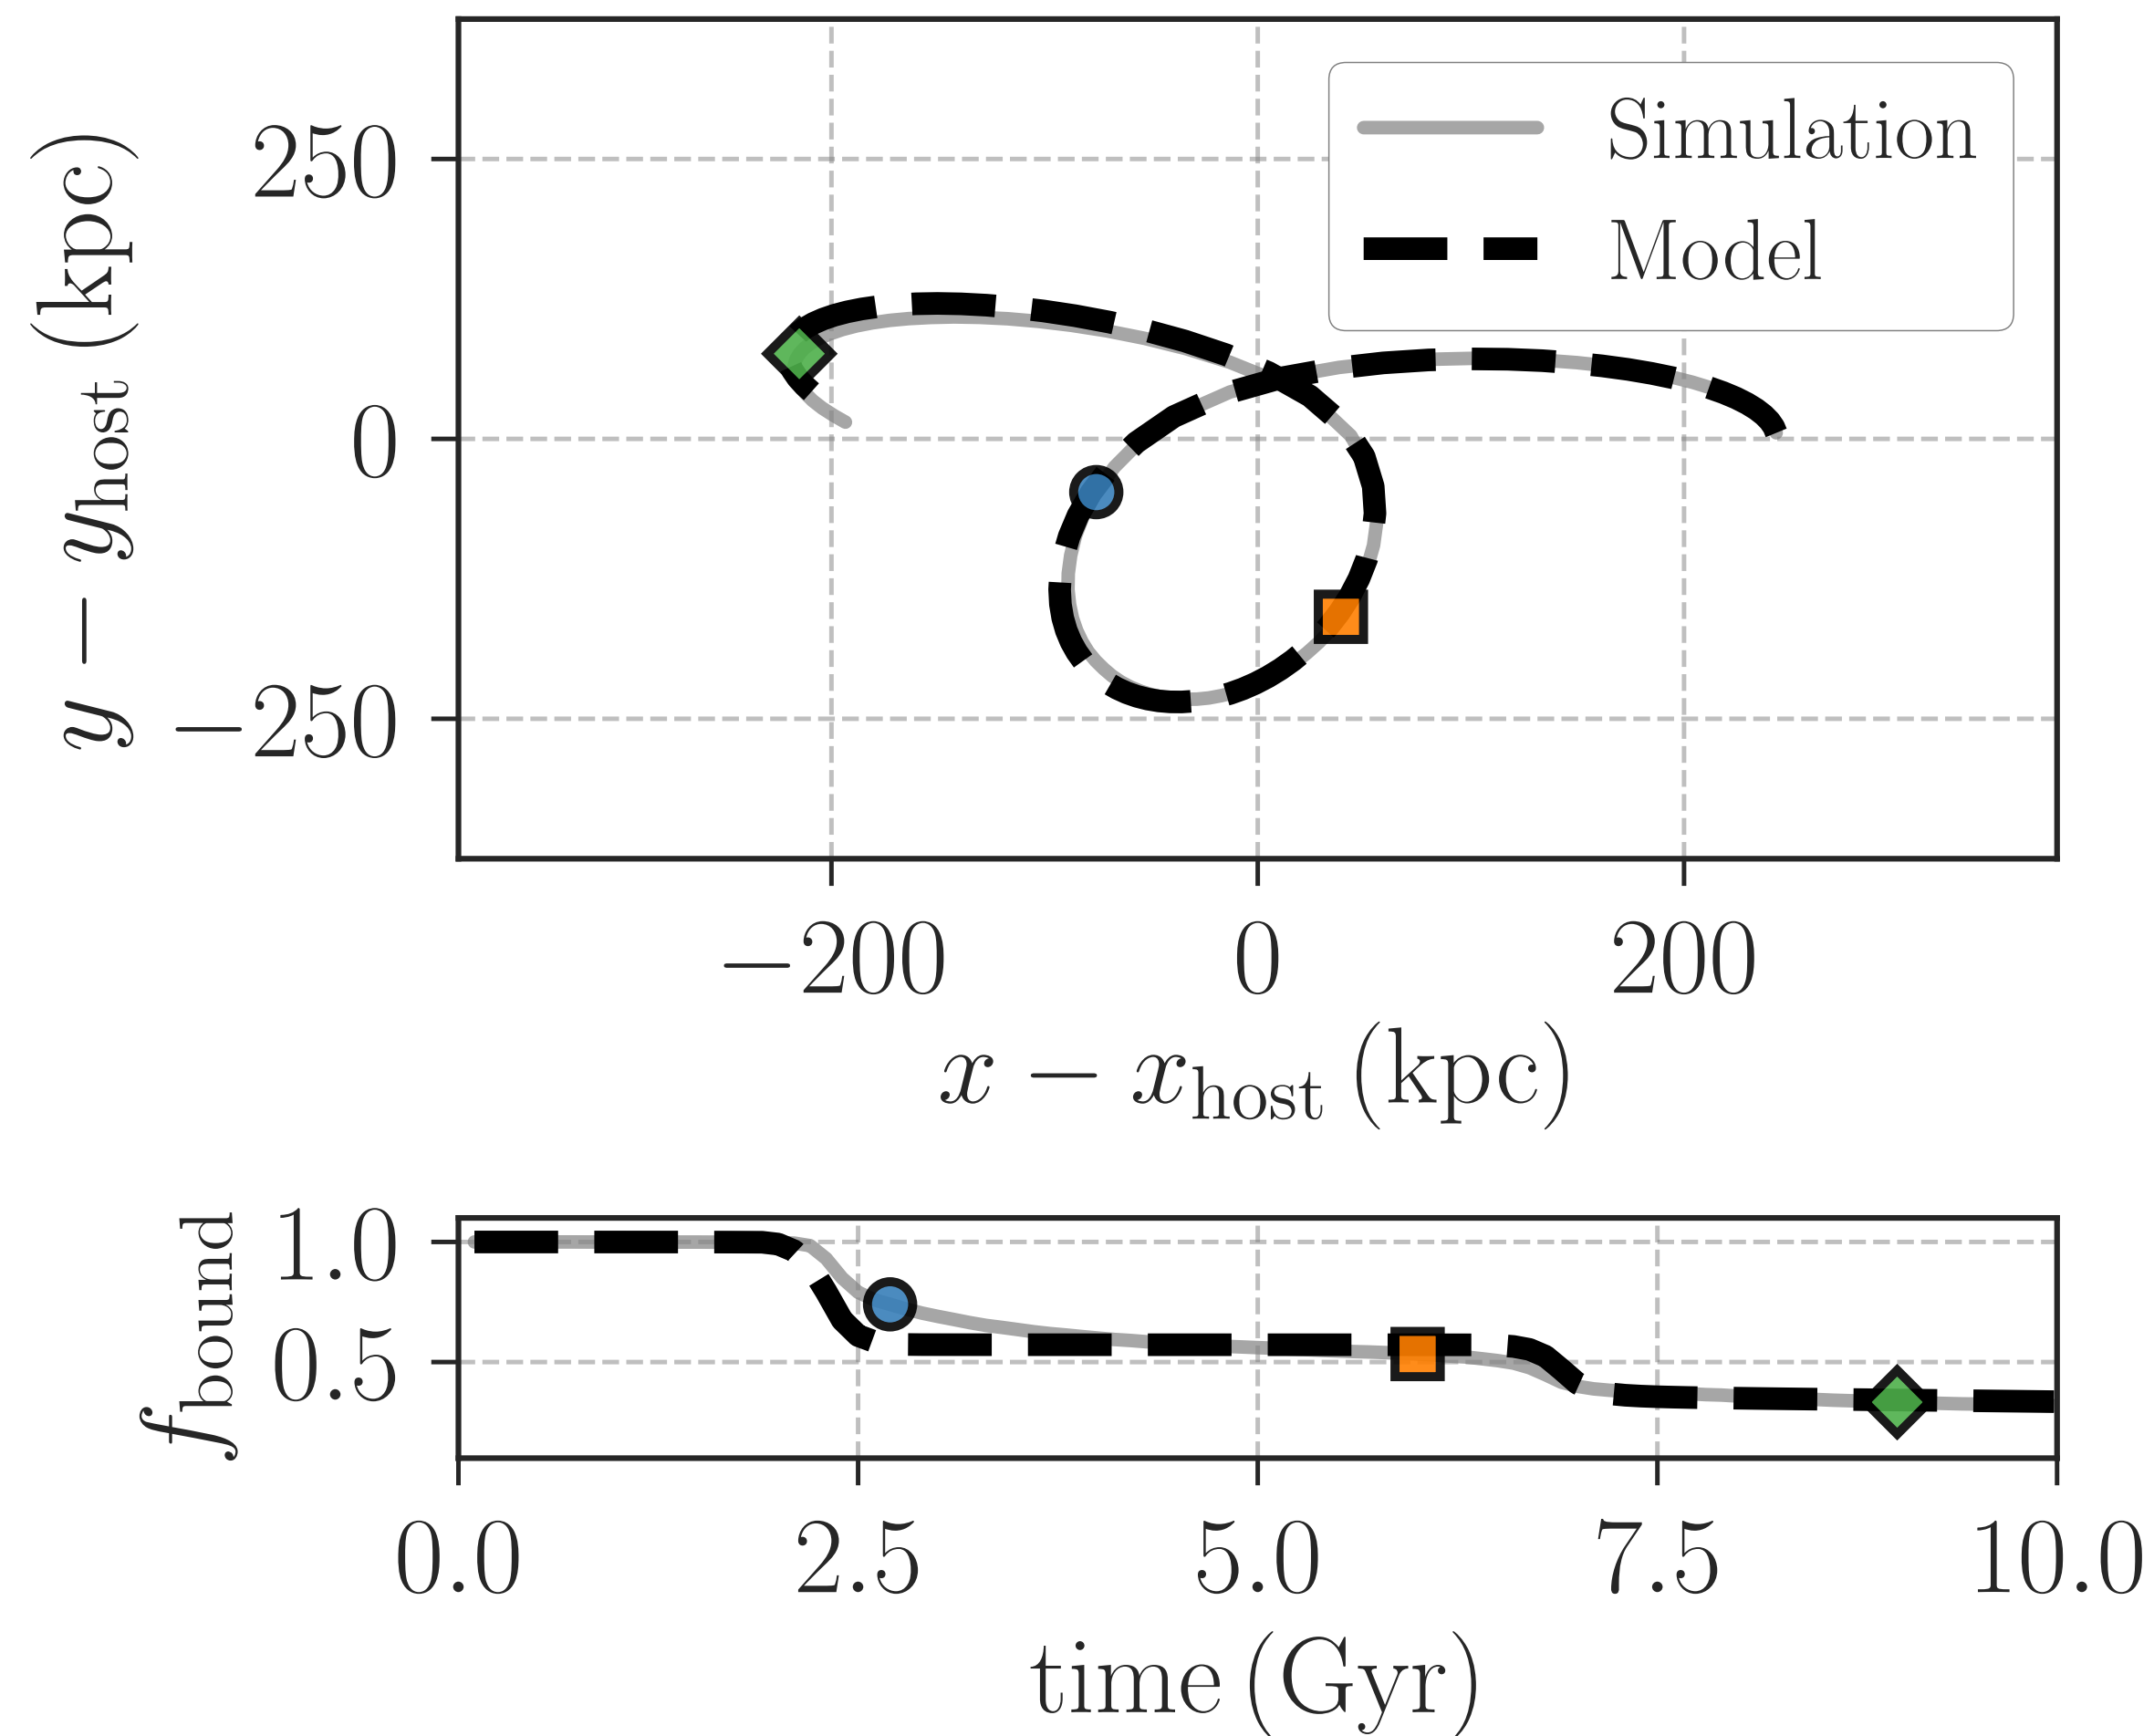

$r_t$  ← tidal radius  
 $\tau_{\text{dyn}}$  ← dynamical time

- $\alpha = 0.55$  can explain the CDM simulation results
- Our simulations indicate that  $\alpha$  depends on  $\sigma/m$
- Found that  $\alpha \simeq 0.65$  provides a best fit to the simulation results with  $\sigma/m = 3 \text{ cm}^2/\text{g}$

# Comparison with our model and simulations

$$\sigma/m = 3 \text{ cm}^2/\text{g}$$

# Summary and outlook

- MW Satellites are powerful targets for constraining the nature of dark matter
- We developed a semi-analytic model of SIDM subhaloes in a MW-sized host with ideal N-body sims
  1. Found a non-trivial effect in the subhalo mass loss rate for the SIDM scenario
  2. Tested our models with sims in details by varying subhalo orbits, SIDM cross sections, initial subhalo profiles
- Next things to do:
  - Comparisons with our model and *cosmological* sims
  - Include the baryonic disc in a host halo
