Jan.15-19,2024

based on a work with Atsushi Kanazawa  
ArXiv:2303.04383

# §1. BCOV formula of Calabi-Yau manifolds

'92 Cecotti, Fendly, Intligator and Vafa introduced a new index for  $N = 2$  SFT in two dimensions,

$$\mathbf{F}_1 = \text{Tr}_{\mathcal{H}}(-1)^F F, \quad F : \text{Fermion number operator}$$

( cf. Witten index  $\text{Tr}_{\mathcal{H}}(-1)^F$  is topological.)

This new index is **not topological**, but it was argued that

- (1)  $\mathbf{F}_1 = \mathbf{F}_1(t, \bar{t})$  splits "almost" to a product  $F(t)\overline{F(\bar{t})}$ , where  $t_1, \dots, t_r$  are holomorphic coordinates of the moduli of  $N = 2$  theory.
- (2) The splitting is not complete, but satisfies the **holomorphic anomaly equation**

$$\frac{\partial}{\partial t_i} \frac{\partial}{\partial \bar{t}_j} \mathbf{F}_1 = \text{Tr}(\mathcal{C}_i \mathcal{C}_{\bar{j}}) + \frac{\chi}{12} g_{i\bar{j}}$$

$\mathcal{C}_i = (C_i^a{}_b)$  describes the operator algebra of the ground states  
 $g_{i\bar{j}}$ : Zamolodchikov metric,  $\chi := \text{Tr}(-1)^F$

- In case of  $N = 2$   $\sigma$ -models on a Calabi-Yau 3 fold  $X$ , using the so-called special Kähler geometry on the (Kähler) moduli, the h.a.e. can be solved as

$$\mathbf{F}_1 = \frac{1}{2} \log \left\{ e^{(3+h_X^{1,1} - \frac{\chi}{12})\mathcal{K}(t, \bar{t})} (\det g_{i\bar{j}})^{-1} |f|^2 \right\}$$

- If we have a family of (mirror) CY 3 folds, which has a LCSL at  $o$  given by

$$x_1 = \cdots = x_r = 0,$$

we have the "topological limit"  $\lim_{\bar{t} \rightarrow \infty} \mathbf{F}_1(t, \bar{t}) := \lim_{\lambda \rightarrow \infty} \mathbf{F}_1(t, \lambda \bar{t})$ , where

$$\mathcal{K}(t, \bar{t}) \longrightarrow -\log(w_0(x)\overline{w_0(x)})$$

$$\det(g_{i\bar{j}})^{-1} \longrightarrow \left| \frac{\partial(x_1, \dots, x_r)}{\partial(t_1, \dots, t_r)} \right|^2$$

**Definiton.** [BCOV formula (of log form) for CY 3 folds]

$$F_1^{top}(t) = \frac{1}{2} \log \left\{ \left( \frac{1}{w_0(x)} \right)^{3+h_X^{1,1} - \frac{\chi}{12}} \frac{\partial(x_1, \dots, x_r)}{\partial(t_1, \dots, t_r)} f(x) \right\}$$

$f(x)$ : holomorphic functions which we determine by suitable boundary conditions

**Discovery.** (BCOV '93) (1) If we find a suitable  $f(x)$ ,  $F_1^{top}(t)$  gives the generating function of genus one Gromov-Witten invariants of  $X$ .  
 (2) This generalizes to the higher genus functions  $\{(F_g^{top}(t), f_g(x))\}_{\geq 2}$  by

$$\frac{\partial}{\partial \bar{t}_i} \mathbf{F}_g(t, \bar{t}) = \frac{1}{2} \partial_{\bar{i}} S^{jk} \left\{ D_j D_k \mathbf{F}_{g-1}(t, \bar{t}) + \sum_{r+s=g} D_j \mathbf{F}_r(t, \bar{t}) D_k \mathbf{F}_s(t, \bar{t}) \right\}$$

with  $\partial_{\bar{i}} S^{jk} = e^{2\mathcal{K}(t, \bar{t})} C_{\bar{i}\bar{j}\bar{k}} g^{\bar{j}j} g^{\bar{k}k}$ .

- This is still mysterious (at least for me) after 30 years since the discovery!
- Also this motivates us studying the moduli spaces of CY manifolds.

The subject of today: BCOV formula  $F_1^{top}(t)$  for K3 surfaces

For K3 surfaces, there are no corrections in  $F_1^{top}$  from Gromov-Witten invariants. However, we observe nice modular forms from it.

- – work with Atsushi Kanazawa ArXiv:2303.04383, Adv.Math(2023).

## §2. Lattice polarized K3 surfaces

$X$  : a K3 surface ( Kähler,  $c_1(T_X) = 0$ ,  $H^1(X, \mathcal{O}_X) = 0$ )

$(H^2(X, \mathbb{Z}), (*, *)) \simeq L_{K3}$  where  $L_{K3} := U^{\oplus 3} \oplus E_8(-1) \oplus E_8(-1)$

$\phi : H^2(X, \mathbb{Z}) \simeq L_{K3}$  is called a marking of K3

### Definitions:

Fix a primitive embedding  $M \hookrightarrow L_{K3}$   
 $(1, \rho - 1) \quad (3, 19)$

•  $(X, \phi) : (\text{marked})$   $M$ -polarized K3  $\Leftrightarrow$   $\phi^{-1}(M) \subset \text{Pic}(X)$   
 $\phi^{-1}(C_M^{\text{pol}}) \subset \text{Amp}(X)$

•  $(X_1, \phi_1) \sim (X_2, \phi_2) \Leftrightarrow \exists f : X_1 \rightarrow X_2 (\text{isom.})$   
s.t. 
$$\begin{array}{ccc} H^2(X_1, \mathbb{Z}) & \xleftarrow[\sim]{f^*} & H^2(X_2, \mathbb{Z}) \\ \phi_1 \downarrow \wr & & \phi_2 \downarrow \wr \\ L_{K3} & \xleftarrow[\sim]{} & L_{K3} \\ \cup & & \cup \\ M & \stackrel{=}{=} & M \end{array}$$

$$\Omega_M = \Omega(M^\perp) := \{[w] \in \mathbb{P}(M^\perp \otimes \mathbb{C}) \mid (w.w) = 0, (w, \bar{w}) > 0\}^+$$

**Period domain**

Moduli space of  
 $M$ -polarized K3 surfaces  $= \Omega_M / O(M, L_{K3})$

$$O(M, L_{K3}) = \{g \in O(L_{K3}) \mid g|_M = id_M, g \text{ acts on } \Omega_M\}$$

### **Mirror symmetry (Dolgachev '96, Todorov '96)**

When we have the decomposition:  $M \oplus M^\perp = M \oplus U \oplus \check{M} \subset L_{K3}$ ,

$M$ -polarized K3 surfaces  $\longleftrightarrow$   $\check{M}$ -polarized K3 surfaces  
 mirror sym.

### **Remark ( $M$ -polarizable K3 surfaces, HLOY '01)**

A slightly larger group acts on the period domain to obtain

$$\{\text{isom. classes of } M\text{-polarizable K3 surfaces}\} = \Omega_M / O(M^\perp)_+$$

if  $M \hookrightarrow L_{K3}$  is unique up to isom., where

$$O(M^\perp)_+ := \{g \in O(M^\perp) \mid g \text{ acts on } \Omega_M\}.$$

### §3. Settings for the BCOV formula

0. Take an embedding  $\check{M} \hookrightarrow L_{K3}$  s.t.  $\check{M} \oplus \check{M}^\perp = \check{M} \oplus U \oplus M \subset L_{K3}$   
 $(1, \check{r} - 1) \quad (1, 1) \quad (1, r - 1)$

1. Suppose we have a family of  $\check{M}$ -polarizable K3 surfaces s.t.

$$\begin{array}{ccc} \check{\mathcal{X}} & \supset & \check{X}_x \\ \pi \downarrow & & \downarrow \\ \mathcal{M} & \ni & x \end{array}$$

the associated local system  $R^2\pi_*\mathbb{C}_{\check{\mathcal{X}}}$  has a boundary point  $o$ , i.e., a LCSL, which is characterized by a certain local solutions

$$w_0(x), w^{(2)}(x), w_1^{(1)}(x), \dots, w_r^{(1)}(x)$$

satisfying a quadratic relation

$$2w_0w^{(2)} + (w^{(1)}, w^{(1)})_M = 0.$$

2. Then we can define the period map by

$$\begin{array}{ccc} \mathcal{P} : \mathcal{M} & \longrightarrow & \Omega_{\check{M}} \\ \cup & & \cup \\ x & \mapsto & \mathcal{P}(x) := [w_0(x), w^{(2)}(x), w_1^{(1)}(x), \dots, w_r^{(1)}(x)] \\ & & = [\int_{\phi^{-1}(e)} \omega_x, \int_{\phi^{-1}(f)} \omega_x, \int_{\phi^{-1}(\gamma_1)} \omega_x, \dots, \int_{\phi^{-1}(\gamma_r)} \omega_x] \end{array}$$

$\{e, f, \gamma_1, \dots, \gamma_r\}$  is a basis of  $\check{M}^\perp = U \oplus M$

3. Define **the mirror map** by introducing the inhomogeneous coordinates

$$\mathcal{P}(x) = [w_0(x), w^{(2)}(x), w_1^{(1)}, \dots, w_r^{(1)}] = [1, -\frac{1}{2}(t^2)_M, t_1, \dots, t_r]$$

which describes the isomorphism

$$\begin{array}{ccc} \Omega_{\check{M}} & \xrightarrow{\sim} & M \otimes \mathbb{R} + \sqrt{-1}C_M \\ \Downarrow & & \Downarrow \\ \mathcal{P}(x) & \mapsto & (t_1, \dots, t_r) \quad : \text{Tube domain coordinates} \\ \Updownarrow & & \Updownarrow \quad (= \text{mirror map}) \\ O(\check{M}^\perp)_+ & & O(\check{M}^\perp)_+ \end{array}$$

Holomorphic functions on the tube domain  $T_M := M \otimes \mathbb{R} + \sqrt{-1}C_M$  with natural transformation properties are called **automorphic forms** of  $O(\check{M}^\perp)_+$ .

4. **Automorphic form on  $T_M$ .**

(1) Write the linear action of  $g \in O(\check{M}^\perp)_+$  by

$$g \cdot (1, -\frac{1}{2}(t^2)_M, t_1, \dots, t_r) = (D(g, t), A(g, t), B_1(g, t), \dots, B_r(g, t)).$$

This induces the action  $g : (t_1, \dots, t_r) \mapsto (g \cdot t_1, \dots, g \cdot t_r)$  by

$$g \cdot t := \frac{B_i(g, t)}{D(g, t)} \quad (i = 1, \dots, r) \quad (\text{"Modular action"})$$

(2) Homomorphic functions  $F(t)$  on  $T_M$  satisfying

$$\boxed{F(g \cdot t) = D(g, t)^w F(t)} \quad (g \in O(\check{M}^\perp)_+)$$

are called **automorphic forms of weight  $w$** .

**Remark.** The period integral  $w_0(x) = w_0(x(t))$  with the mirror map  $x = x(t)$  defines an automorphic form of weight one (with possibly a multiplier  $v(g)$ ), i.e., it holds that

$$\boxed{w_0(x(g \cdot t)) = v(g) D(g, t) w_0(x(t))} \quad (|v(g)| = 1)$$

**Definition** (H.K. '23) We define **BCOV formula** by

$$\tau_{BCOV}(t) := \left\{ \left( \frac{1}{w_0(x)} \right)^{r+1} \frac{\partial(x_1, \dots, x_r)}{\partial(t_1, \dots, t_r)} \prod_i dis_i^{r_i} \prod_i x_i^{-1+a_i} \right\}$$

where  $r_i$  and  $a_i$  are parameters to be fixed by boundary conditions.

If  $(\tau_{BCOV}(t))^{-1}$  defines a cusp form on  $T_M = M \otimes \mathbb{R} + \sqrt{-1}C_M$ , we call it

**BCOV cusp form.**

## Lemma.

The Jacobian factor  $\frac{\partial(x_1, \dots, x_r)}{\partial(t_1, \dots, t_r)}$  has weight  $r$  (with possibly a multiplier system) w.r.t.  $O(\check{M}^\perp)_+ (= O(U \oplus M)_+)$ .

Proof) Recall that  $\Omega_{\check{M}} \simeq M \otimes \mathbb{R} + \sqrt{-1}C_M$  is described by a quadric

$$\{[u, v, z] \mid 2uv + (z, z)_M = 0\} \subset \mathbb{P}(\check{M}^\perp \otimes \mathbb{C}).$$

Using this, we can show that

$$\begin{aligned} \frac{u^r}{2} dt_1 \wedge dt_2 \wedge \dots \wedge dt_r &= \text{Res} \left( \frac{d\mu_{\mathbb{P}^{r+1}}}{2uv + (z, z)_M} \right) \\ &= \text{Res} \left( \frac{d\mu'_{\mathbb{P}^{r+1}}}{2u'v' + (z', z')_M} \right) = \frac{u'^r}{2} dt'_1 \wedge dt'_2 \wedge \dots \wedge dt'_r \end{aligned}$$

Here we can identify  $\frac{u'}{u}$  with the automorphic factor  $D(g, t)$ .  $\square$

## Proposition.

The inverse power  $(\tau_{BCOV}(t))^{-1}$  of the BCOV formula

$$\tau_{BCOV} = \left( \frac{1}{w_0(x)} \right)^{r+1} \frac{\partial(x_1, \dots, x_r)}{\partial(t_1, \dots, t_r)} \prod_k dis_k^{r_k} \prod_i x_i^{-1+a_i}$$

has weight one with respect to  $O(\check{M}^\perp)_+$ .

Proof) The period integral  $w_0(x(t))$  has weight **one** as we remarked.

Since, the Jacobian has weight  $\mathbf{r}$ , the weight of  $(\tau_{BCOV})^{-1}$  is one.  $\square$

## Boundary conditions:

We determine the parameters  $r_k$  and  $a_i$  by the following regularity conditions:

(1) **Conifold regularity**  $\dots$  a regularity at the discriminant loci  $\{dis_k(x) = 0\}$ .

$\rightarrow$  it turns out  $\mathbf{r}_k = -\frac{1}{2}$  in general

(2) **Orbifold regularity**  $\dots$  a regularity from the so-called orbifold points.

$\rightarrow$  case by case

**Example 1.**  $(6) \subset \mathbb{P}^3(3,1,1,1)$  ( $M_2 = \langle 2 \rangle$ -polarized K3 surface)  $\rightarrow M_2 \oplus U \oplus \check{M}_2$   
 $\check{M}_2 = \langle -2 \rangle \oplus U \oplus E_8(-1)^{\oplus 2}$ -polarizable K3 surfaces  $\subset L_{K3}$   
(a Picard rank 19 family of K3 surfaces)

1. Picard-Fuchs equation  $\{\theta_x^3 - 8x(6\theta_x + 5)(6\theta_x + 3)(\theta_x + 1)\}w(x) = 0$
2. mirror map  $x(t) = \frac{1}{j(t)}$ ,  $w_0(x) = E_4(t)^{\frac{1}{2}}$
3.  $\left(\frac{1}{w_0(t)}\right)^2 C_{xx} \left(\frac{dx}{dt}\right)^2 = 2$ , where  $C_{xx} = \frac{2}{x^2(1-1728x)}$  is the Griffiths-Yukawa coup.  
mirror
4.  $\tau_{BCOV}(t) = \left(\frac{1}{w_0(t)}\right)^2 \left(\frac{dx}{dt}\right) dis_0^{r_0} x^{-1+a}$ , where  $dis_0 = 1 - 1727x$

Form the 3rd relation, we have  $\frac{dx}{dt} = w_0(x)x(1-1728x)^{\frac{1}{2}}$ .

Using this (and after a little calculations), we find

$$\boxed{(\tau_{BCOV}(t))^{-1} = (\eta(t)^{24})^{\frac{1}{6}}} \leftarrow \text{a cusp form!}$$

for  $r_0 = -\frac{1}{2}$  and  $a = -\frac{1}{6}$  (justified by the orbifold regularity).

In this (trivial) case, we obtain a **BCOV cusp form** from  $\tau_{BCOV}(t)$ . 12

**Example 2.** ( $M_{20} \oplus U \oplus \check{M}_{20}$  from the list in Lian and Yau '93)

$\check{M}_{20} = \langle -20 \rangle \oplus U \oplus E_8(-1)^{\oplus 2}$ -polarizable K3 surfaces

(a Picard rank 19 family of K3 surfaces)

1. Picard-Fuchs equation

$$\{\theta_x^3 - 2x(2\theta_x + 1)(3\theta_x^2 + 3\theta_x + 1) - x^2(4\theta_x + 3)(4\theta_x + 4)(4\theta_x + 5)\} w = 0$$

2. mirror map  $x(t) = q - 4q^2 - 6q^3 + 56q^4 - 45q^5 + \dots$  (**Thompson series** of  $\Gamma_0(10)_+$ )

3.  $\left(\frac{1}{w_0(t)}\right)^2 C_{xx} \left(\frac{dx}{dt}\right)^2 = 20$ , where  $C_{xx} = \frac{20}{x^2(1+4x)(1-16x)}$

$$\Gamma_0(n) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2, \mathbb{Z}) \mid c \equiv 0 \pmod{n} \right\}$$

### Proposition.

The conifold and orbifold regularities uniquely determine the parameters

in  $\tau_{\text{BCOV}}$  as  $r_0 = r_1 = -\frac{1}{2}$  and  $a = -\frac{3}{4}$ . Then, we have

$$\tau_{\text{BCOV}}(t) = \left(\frac{1}{w_0(x)}\right)^2 \frac{dx}{dt} \text{dis}_0^{r_0} \text{dis}_1^{r_1} x^{-1+a} = \frac{1}{\eta_1(t)\eta_2(t)\eta_5(t)\eta_{10}(t)},$$

and  $(\tau_{\text{BCOV}}(t))^{-1}$  defines a BCOV cusp form on  $\mathbb{H}_+$  w.r.t.  $\Gamma_0(10)_+$ .

Here we define  $\eta_k(t) := \eta(kt)$ .

Similar calculations apply to other cases of the  $\check{M}_{2n}$ -polarizable K3 surfaces in the list of Lian and Yau ('93). We can verify the following results for all cases in the list, which we state as a conjecture in general:

**Conjecture.** (H.K. '23)

For families of  $\check{M}_{2n} = \langle -2n \rangle \oplus U^{\oplus 2} \oplus E_8(-1)^{\oplus 2}$ -polarizable K3 surfaces over  $\mathbb{P}^1$ , we have the BCOV cusp forms

$$(\tau_{BCOV}(t))^{-1} = \eta_{BCOV}(t)$$

with the eta products,

$$\eta_{BCOV}(t) = \left( \prod_{r|n} \eta_r(t)^{\pm 1} \right)^w,$$

where  $+1$  is taken when  $(r, n/r) \neq 1$  and  $-1$  when  $(r, n/r) = 1$ .

**Supporting evidence.** The eta product  $\eta_{BCOV}(t)$  defines a cusp form of the genus zero group  $\Gamma_0(n)_+$  if  $\#\text{cusps}(\Gamma_0(n)_+) = 1$ .

## List of genus zero groups of type $\Gamma_0(n)_+$ (Conway-Norton '79).

$c$  := the number of cusps in  $\mathbb{H}/\Gamma_0(n)_+$

type: the name for the conjugacy classes of the Monster group

Some selected examples of the eta-products  $\eta_{BCOV}(t)$  :

$$\underline{\Gamma_0(10)}_+ \quad \eta_{BCOV}(t) = \eta_1(t)\eta_2(t)\eta_5(t)\eta_{10}(t)$$

$$\underline{\Gamma_0(16)}_+ \quad \eta_{BCOV}(t) = \frac{\eta_2(t)^4\eta_4(t)^4\eta_8(t)^4}{\eta_1(t)^4\eta_{16}(t)^4}$$

$$\underline{\Gamma_0(29)}_+ \quad \eta_{BCOV}(t) = \eta_1(t)^2\eta_{29}(t)^2$$

$$\underline{\Gamma_0(36)}_+ \quad \eta_{BCOV}(t) = \frac{\eta_2(t)^4\eta_3(t)^4\eta_6(t)^4\eta_{12}(t)^4\eta_{18}(t)^4}{\eta_1(t)^4\eta_4(t)^4\eta_9(t)^4\eta_{36}(t)^4}$$

$$\underline{\Gamma_0(94)}_+ \quad \eta_{BCOV}(t) = \eta_1(t)\eta_2(t)\eta_{47}(t)\eta_{94}(t)$$

⋮

• If we assume the conjecture, **K3** differential operators follow:

If we postulate the conjecture, then the following relations follow:

a)  $w_0(x) = x^\gamma \eta_{BCOV}(t)$

b)  $\frac{1}{x(t)} = T_n(t) + c_n$  ( the Thompson series of  $\Gamma_0(n)_+$  )

for all the genus zero group  $\Gamma_0(n)_+$ .

1. We determine  $\gamma$  by requiring the  $q$ -series expansion

$$w_0(x) = 1 + a_1q + a_2q^2 + \dots$$

2. Substituting the inverse series  $q = x + s_1x + s_2x^2 + \dots$  of

$1/x(t) = T_n(t) + c_n$  into the above  $q$  series of  $w_0(x)$ , we obtain

$$w_0(x) = 1 + c_1x + c_2x^2 + c_3x^3 + \dots \quad (*)$$

Searching differential operators which annihilate the series (\*), we **find** 3rd order differential operators for all genus one groups  $\Gamma_0(n)_+$ .

→ **K3 differential operators**

**Proposition.** (H.K.2023)

Assume the conjecture, then we have K3 differential operators of 3rd order for **all** genus zero groups of type  $\Gamma_0(n)_+$ .

**An example of K3 differential operator:** (for the case  $\Gamma_0(36)_+$ )

$$\begin{aligned} \mathcal{D}_{36A} = & \theta_x^3 - x(3\theta_x + 1)(3\theta_x^2 + 2\theta_x + 1) - 6x^2\theta_x(12\theta_x^2 - 3\theta_x - 1) \\ & + 2x^3\theta_x(284\theta_x^2 + 405\theta_x + 199) + 6x^4\theta_x(1156\theta_x^2 + 75\theta_x + 89) \\ & - 6x^5\theta_x(11927\theta_x^2 + 10401\theta_x + 4939) \\ & + 18x^6(8968\theta_x^3 + 11586\theta_x^2 + 5960\theta_x + 2553) \\ & + 18x^7(11788\theta_x^3 + 14184\theta_x^2 - 5086\theta_x - 19947) \\ & - 27x^8(30109\theta_x^3 + 44628\theta_x^2 + 7040\theta_x - 6990) \\ & - 27x^9(19871\theta_x^3 + 39147\theta_x^2 + 9715\theta_x + 29949) \\ & + 486x^{10}(2664\theta_x^3 + 4503\theta_x^2 + 2623\theta_x + 561) \\ & + 486x^{11}(2892\theta_x^3 + 6453\theta_x^2 + 5465\theta_x + 1657) + 360126x^{12}(\theta_x + 1)^3. \end{aligned}$$

$$\left\{ \begin{array}{cccccc} -1 & 0 & \frac{1}{3} & -1 - \frac{2\sqrt{3}}{3} & -1 + \frac{2\sqrt{3}}{3} & \infty \\ 1 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & \frac{1}{2} & \frac{1}{2} & 1 \\ 1 & 0 & 1 & 1 & 1 & 1 \end{array} \right\} \text{Riemann's } \mathcal{P} \text{ scheme}$$

the number of the cusps is 4, which coincides with the general formula.

## §4. Clingher-Doran's family of K3 surfaces

- Clingher and Doran ('12) studied a special quartic  $\{f = 0\} \subset \mathbb{P}^3$  with

$$f = y^2 zw - 4x^3 z + 3\alpha xzw^2 + \beta zw^3 + \gamma xz^2 w - \frac{1}{2}(\delta z^2 w^2 + w^4).$$

- They found that

(1) When  $\gamma \neq 0$ ,  $\{f = 0\}$  is a  $\check{M} = \mathbf{U} \oplus \mathbf{E}_8(-1) \oplus \mathbf{E}_7(-1)$ -polarized K3 surface.

(2) The parameter space

$$\mathcal{M}_{CD} := \{[\alpha, \beta, \gamma, \delta] \in \mathbb{W}\mathbb{P}^3(2, 3, 5, 6) \mid \gamma \neq 0 \text{ or } \delta \neq 0\}$$

describes a **coarse** moduli space of the  $\check{M}$ -polarized K3 surfaces.

**Note.** (i)  $\Omega_{\check{M}} = \{[w] \in \mathbb{P}(\check{M}^\perp \otimes \mathbb{C}) \mid (w, w) = 0, (w, \bar{w}) > 0\}^+$   
 $\simeq \mathbb{H}_2$     **the Siegel upper half space of genus two**

(ii)  $O(\check{M}^\perp)_+ / \{\pm I_5\} \simeq Sp(4, \mathbb{Z}) / \{\pm I_4\}$

(iii)  $\mathcal{P} : \mathcal{M}_{CD} \rightarrow \mathbb{H}_2$  (period map)

**cf. Weierstrass normal form:**  $y^2 = 4x^3 - g_2x - g_3$  with  $[g_2, g_3] \in \mathbb{W}\mathbb{P}^1(2, 3)$ <sup>19</sup>

**Theorem.**(Clingher-Doran, '13)

$$\mathcal{P}^{-1}(\tau) = [\mathcal{E}_4(\tau), \mathcal{E}_6(\tau), 2^{12}3^5\chi_{10}(\tau), 2^{12}3^6\chi_{12}(\tau)]$$

where  $\mathcal{E}_4$  and  $\mathcal{E}_6$  are genus two Eisenstein series of weight four and six, and  $\chi_{10}$  and  $\chi_{12}$  are Igusa's cusp forms of weight ten and twelve, respectively.

**Problem:** Determine the BCOV cusp form in this case

To calculate the BCOV cusp forms, we need a family of K3 surfaces with **a special boundary point (LCSL)**.

**Results:**

1. We can represent  $\{f = 0\} \subset \mathbb{P}^3$  by  $\{f_\Delta = 0\} \subset \mathbb{P}_\Delta$ ,  $\Delta$ : reflexive polytope.
2. Using  $\text{Aut}(\mathbb{P}_\Delta) \supsetneq (\mathbb{C}^*)^3$ , we can transform  $\{f_\Delta = 0\}$  to  $\{F_\Delta = 0\}$  for which we **find Picard-Fuchs equations and a LCSL**.

–In fact, this is exactly in the frame work of the extended GKZ system introduced in HKTY ('93) and HLY ('95).

## Proposition. (H.K.'23)

- (1) The **conifold regularity** condition determines the parameters  $r_k = -\frac{1}{2}$ .
- (2) There are **two** orbifold points  $A$  and  $B$ . Imposing the **orbifold regularity** for each, we obtain,

$$(\tau_{BCOV}(t))^{-1} = \begin{cases} (\chi_{10}(\tau))^{\frac{1}{10}} & \text{for } A \\ (3\chi_{12}(\tau) + \chi_{10}(\tau)\mathcal{E}_4(\tau)^{\frac{1}{2}})^{\frac{1}{12}} & \text{for } B \end{cases}.$$

## Remark.

(i) When  $\tau_{12} \rightarrow 0$  in  $\tau = \begin{pmatrix} \tau_{11} & \tau_{12} \\ \tau_{12} & \tau_{22} \end{pmatrix}$ ,

$$\chi_{10}(\tau) \longrightarrow 0, \quad \chi_{12}(\tau) \longrightarrow \eta(\tau_{11})^{24}\eta(\tau_{22})^{24}$$

(ii) When  $\tau_{12} \rightarrow 0$ , the Picard lattice of  $\check{M}$ -polarized K3 surfaces extends to

$U \oplus E_8(-1)^{\oplus 2}$ , or the orthogonal lattice reduces

$$\check{M}^\perp = U^{\oplus 2} \oplus \langle -2 \rangle \longrightarrow U^{\oplus 2}$$

## §5. Summary and some other aspects

**Summary:** BCOV formula of K3 surfaces  $\rightarrow$  BCOV cusp forms

$$\tau_{BCOV} = \left( \frac{1}{w_0(x)} \right)^{r+1} \frac{\partial(x_1, \dots, x_r)}{\partial(t_1, \dots, t_r)} \prod_k dis_k^{r_k} \prod_i x_i^{-1+a_i}$$

1. (Vector-valued) **quasi-automorphic forms** follow from  $\tau_{BCOV}(t)$ :  
— for elliptic curves, we have  $(\tau_{BCOV}(\tau))^{-1} = \eta(\tau)^2$  and

$$\frac{\partial}{\partial \tau} \log(\tau_{BCOV}(\tau))^{-1} = \frac{1}{12} E_2(\tau)$$

- for K3 surfaces, we have the **propagators**

$$S^a(t) = \sum_b K^{ab} \frac{\partial}{\partial t_b} \log(\tau_{BCOV}(t))^{-1}$$

2. Conjectured relation to the Ray-Singer analytic torsion.
3.  $\tau_{BCOV}(t)$  for Calabi-Yau 3 folds and  $\{(F_g(t), f_g(t))\}_{g \geq 2}$
