

Hilbert schemes and the Le Bruyn-Procesi theorem

Monday, 18 December 2023 15:30 (50 minutes)

For a positive integer n and a finite subgroup Γ in $SL(2, \mathbb{C})$, I'll describe work in preparation with Ryo Yamagishi which shows that the Hilbert scheme of n -points on \mathbb{C}^2/Γ is reduced. In fact, it's isomorphic to a Nakajima quiver variety, so it has symplectic singularities and it admits a unique crepant resolution. This strengthens previous joint work of mine with Gammelgaard, Gyenge and Szendroi. The main tool is a generalisation of the Le Bruyn-Procesi theorem which describes the invariant algebra for the natural action of the product of general linear groups on the space of representations of a quiver for a given dimension vector.
