Co-funded by the European Union

Classification of ESSνSB WC Near Detector Events Using Graph Neural Networks

ν_μ- and ν_e-events for neutrino oscillation studies

Kaare Endrup Iversen - Lund University

Outline

- ESSνSB - An accelerator neutrino experiment in Sweden
- GNN Implementation

- Classification Performance
- Generalisation

LLH Based Reconstruction

fiTQun
J. Phys.: Conf. Ser. 888 012066, 2017

Challenges

- Likelihood reconstruction takes ~1 CPU min/event
- To explore different detector proposals, fast reconstruction is crucial

ESS neutrino Super Beam plus

LUND UNIVERSITY

Why Do We Need GNN Reconstruction?

- Fast and reliable event reconstruction enables testing of different detector layouts
- LLH-based methods are accurate, but reconstruction is slow
- Multiple reconstruction methods provides a way to cross check and find systematic errors

ESS neutrino Super Beam plus

LUND UNIVERSITY

Data processing

- Cuts based on reconstructed variables
- Removes events that are hard to classify
- Reduces events by a factor ~2

Event Classification Performance

- The GNN has acceptable performance even on the full events
- Using the GNN, the data cuts can be made obsolete

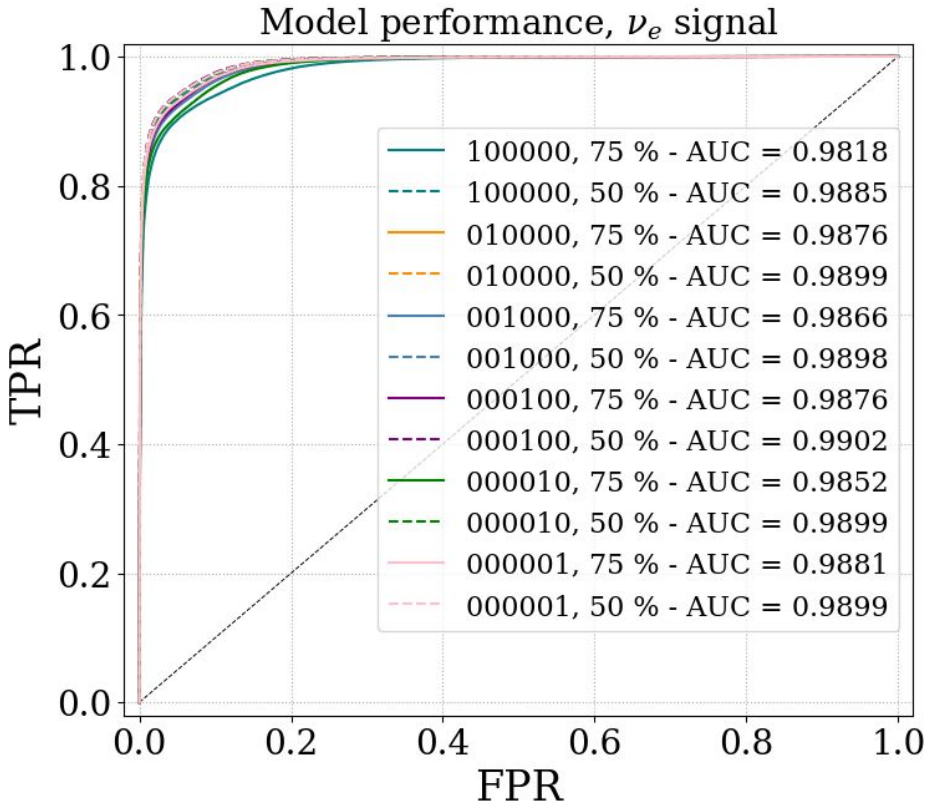
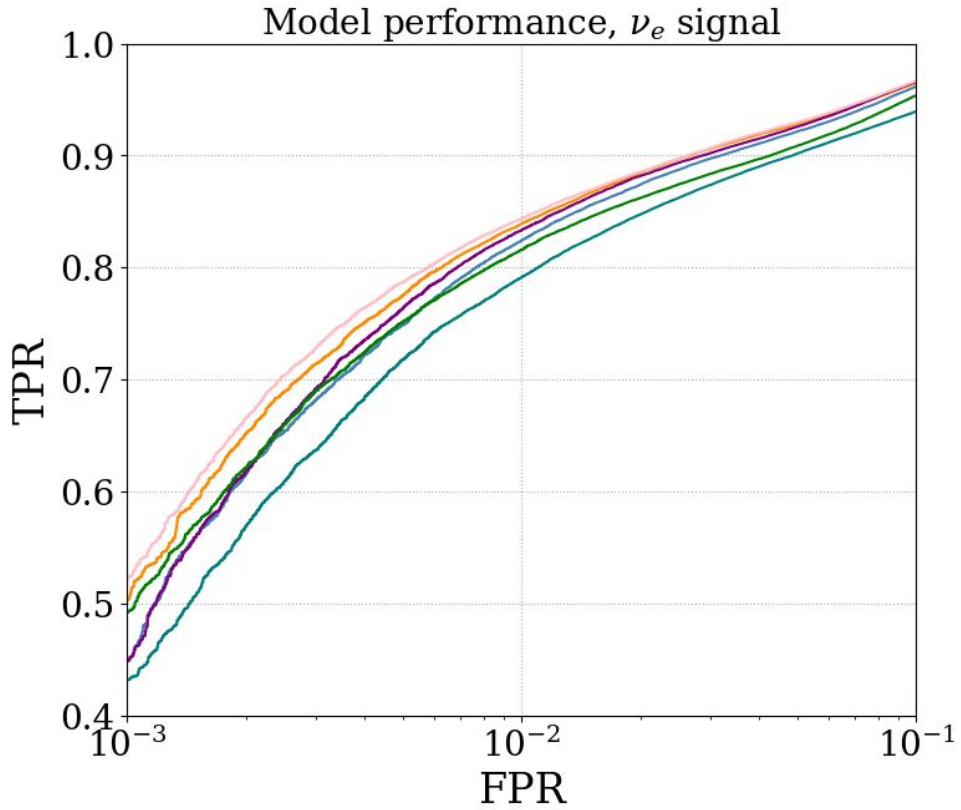
But which event topologies?

Generalisation





Summary

- nGNNs can match fiTQun and outperform on difficult topologies
- Fast reconstruction can aid detector design - not all PMTs are created equal

Event Classification - Performance Measures

The neutrino beam will consist of > 98 % muon neutrinos (at the near detector)

- We can allow more electron neutrino events to be misidentified and still have a pure muon neutrino event sample

Event Classification - Performance Measures

The neutrino beam will consist of > 98 % muon neutrinos (at the near detector)

- We can allow more electron neutrino events to be misidentified and still have a pure muon neutrino event sample

False positive rate (FPR) is the ratio of undesired events are identified as the desired type

- Example: The **FPR** for **electron neutrino** events is the number of **muon neutrino** events identified as **electron neutrinos**, divided by the total number of **muon neutrino** events

Event Classification - Performance Measures

The neutrino beam will consist of > 98 % muon neutrinos (at the near detector)

- We can allow more electron neutrino events to be misidentified and still have a pure muon neutrino event sample

False positive rate (FPR) is the ratio of undesired events are identified as the desired type

- Example: The **FPR** for **electron neutrino** events is the number of **muon neutrino** events identified as **electron neutrinos**, divided by the total number of **muon neutrino** events

We select samples that yield FPRs of:

- **1 % for muon neutrinos**
- **0.1 % for electron neutrinos**
